2. PERFORMANCE CURVES

2-1 AC OUTPUT

- 50Hz/60Hz—220V Type
  OUTPUT
  Max. . . . 550W/50Hz, 650W/60Hz
  Rated . . 450W/50Hz, 550W/60Hz

- 60 Hz—120V Type
  OUTPUT
  Max. .............. .650W
  Rated ................ 550W

2-2 DC OUTPUT

Rated voltage ............. 12V
Rated current ............ 8.3A
Rated output ............ 100W
3. **FEATURES**

- Exhaust Fan Cooling System for low body temperatures, low noise, longer engine life and reliable performance.
- Large 78 cc 4-Stroke Engine provides enough power for constant 550W (at 60 Hz) rated output.
- Simple One-Touch Engine Control Switch with the engine and fuel on/off levers and choke all integrated into one switch.
- Easy and Reliable Starting with pointless ignition. This generator is also a brush-less type generator for maintenance-free operation.
- Simple Design for a clean appearance and easy maintenance.
- Compact and Lightweight with an easy one-hand carrying handle grip. This generator also offers a high power-to-weight ratio and economical operation.
- Circuit Breaker Protection for safe operation. Replacement of fuses is not necessary in case of an overload.
- Unique Dual Output Design so that two separate A.C. and D.C. electrical appliances can be used at the same time.
- Frequency Changeover Switch enables changing output frequency from 50 Hz to 60 Hz.
- Optional Oil Warning System automatically stops the engine if the oil level drops below the lower limit. (Factory Option)
- Resistor Spark Plug is used as standard to prevent radio frequency noise.
- Standard Tools are attached in the base plate for easy maintenance.
- AC Voltmeter is a standard equipment for monitoring output voltage.

4-2 LOCATION OF SERIAL NUMBER, SPECIFICATION AND SPECIFICATION NUMBER

The serial number is stamped on the crankcase at the opposite side of the carburetor and also stamped on the label stuck above the oil filler cap. The specification and specification number are shown on the nameplate located on the rear cover. Always specify these numbers when inquiring about the generator or ordering parts in order to get correct parts and accurate service.

Fig. 4-7
5. CONSTRUCTION AND FUNCTION OF THE GENERATOR

5-1 CONSTRUCTION

Fig. 5-1
5-2 FUNCTION OF EACH COMPONENT

5-2-1 GENERATOR

(1) STATOR
The stator consists of a laminated silicon steel sheet core, a main coil and condenser coil which are wound in the core slots.
AC and DC output are taken out from the main coil. (DC output is taken out from the part of main coil which is in the middle of the main coil.)
The condenser coil excites the stator field coil which generates AC output in the main coil.

(2) CONDENSER
The condenser is mounted on the rear housing and is connected to the condenser coil which is wound in the stator. The condenser coil magnetizes the rotor which increases the density of magnetic flux.

(3) RECTIFIER
The rectifier is also mounted on the rear housing and it converts AC current output from the main coil to DC current. The DC output from the diode of this rectifier is connected to the DC terminal.

(4) ROTOR
The rotor consists of a lamination silicon steel sheet core and field coil which is wound over the core.
DC current in the field coil magnetizes the steel sheet core.
Two permanent magnets are provided at 90 degrees from the poles for the primary exciting action.
A securely mounted fan is pressure-fitted on the end of the rotor shaft to cool the individual coils, iron cores, rectifier, and other integral parts.
Cooling air from the fan is drawn in from the ventilation vents in the rear housing, and is discharged from the exhaust port in the front housing.

(5) CONTROL PANEL
The panel on the front of the housing has a receptacle with a ground terminal and AC output is taken out with a male plug.
DC output is taken out from the red (positive, +) and black (negative, −) terminals.
Control switch, circuit breaker, voltmeter and pilot lamp are installed on the control panel.
5-2-2 ENGINE

(1) CYLINDER and CRANKCASE
The cylinder and the crankcase of the engine are of a one-piece aluminum die-cast design. The cast iron cylinder liner is molded inside the cylinder. Both the intake and exhaust ports are positioned at the lateral side of the cylinder and these parts are formed by using a mold with die-cast cores. The crankcase has its joint face located on the generator side.

(2) MAIN BEARING COVER
The main bearing cover is aluminum die-cast and is mounted on the generator side. By removing the main bearing cover, the interior of the engine can be inspected.

(3) CRANKSHAFT
The crankshaft is constructed of forged carbon steel. The crankpin is induction-hardened and has a press-fitted crank gear located on the generator side of the engine.

(4) CONNECTING ROD and PISTON
The connecting rod is constructed of forged aluminum alloy with both the large and small ends utilized as bearings. The oil scraper and large end cap are molded together. The aluminum alloy casting piston has two compression rings and one oil ring.

(5) CAMSHAFT
The camshaft is constructed of special cast iron and has intake and exhaust valve drive cams, each of which engages with the cam gear. An exclusive aluminum alloy is used on each end of the camshaft in the place of bearings.

(6) VALVE ARRANGEMENT
The intake valve is installed at the oil port side and the exhaust valve at the generator side.

(7) CYLINDER HEAD
The cylinder head is die-cast aluminum and has Ricardo type combustion chamber featuring greater volume capacity for improved combustion efficiency. For easier spark plug maintenance, the cylinder head is positioned at an angle to allow greater access.

(8) GOVERNOR
The centrifugal weight type governor ensures constant engine speed, regardless of load fluctuations (the governor is mechanically linked to the governor drive gear).

(9) EXHAUST FAN COOLING SYSTEM (See Fig. 5-5.)
Instead of blowing outside air on the engine, the Exhaust Fan Cooling System of this generator intakes the cool air and forces the hot air outside from one outlet. This keeps the body temperature lower for greater safety and extends service life.

(10) LUBRICATION SYSTEM
The moving and sliding parts inside the engine are lubricated with the oil scraper fitted on the connecting rod. As the crankshaft rotates, the connecting rod moves up and down and the oil scraper moves in conjunction with the connecting rod movements to scrape up oil in the crankcase and splash it over the surfaces of the moving and sliding parts.
(11) IGNITION
A flywheel/magneto ignition system is employed with the ignition timing set at 23° before top dead center. The magneto is composed of the flywheel and ignition coil with the flywheel mounted on the rotor shaft. The ignition coil is fitted to the front housing.

(12) CARBURETOR
The horizontal draft type carburetor is installed so that the engine will provide excellent starting, good acceleration, low fuel consumption, and superior output. [For details concerning carburetor construction, see the paragraph dealing with carburetor construction and disassembly/assembly (Page 59).]

(13) AIR CLEANER
The air cleaner is a semi-wet type and contains a sponge element.

Fig. 5-5
5-3 DESCRIPTION OF GENERATOR OPERATION

5-3-1 GENERATION OF NO-LOAD VOLTAGE

1) When the generator starts turning the permanent magneto built-in to the flywheel, it generates 1 to 4V of AC voltage in the main coil and condenser coil.

2) The condenser coil is connected to a condenser. So, when a voltage is generated in the condenser coil, minimum current A flows in the condenser coil. At this time, small flux is produced, with which the magnetic force of the rotor's magnetic pole is intensified. When this magnetic force is intensified, the respective voltages in the main coil and condenser coil rise. Current A flowing in the condenser coil increases, with the magnetic flux density of the rotor's magnetic pole increasing further. Also, the main coil voltage and condenser coil voltage increases. These voltage continue rising as this process is repeated.

3) As current flows in the condenser coil, the magnetic flux density in the rotor changes. AC voltage is induced in the field coil when the magnetic flux density varies. Successively, AC current is rectified by the rectifiers connected to both ends of the field coil, and DC current B flows in the field coil. With this current, the rotor core is magnetized, allowing the generator to output steady voltage.

4) When generator speed reaches 2000 to 2300 rpm (50 Hz specification) or 3000 to 3300 rpm (60 Hz specification), the current in the condenser coil and field coil increases rapidly. This acts to stabilize the respective coil output voltages. If generator speed further rises to the rated value, the generator output voltage will reach the rated value.

5-3-2 VOLTAGE FLUCTUATIONS UNDER LOAD

When load current C flows from the generator to the electrical equipment, the magnetic flux which is produced as current C flows in the main coil, this flux serves to increase current A flowing in the condenser coil. With current A increased, the magnetic flux density across the rotor core rises. As a result, the current flowing in the field coil increases, and the generator output voltage is prevented from decreasing.
5-3-3 DC OUTPUT

DC output is taken out from the main coil and is fed to the diode at which time the output undergoes full-wave rectification prior to being supplied to the load connected to the generator. The diode rectifier works to allow the current to flow in direction but does not allow the current to flow in direction as shown in Fig. 5-7.

Fig. 5-8 shows the DC output circuit of the generator.

DC voltage is generated in the main coil; when the voltage in A is higher than that in C, current flows in the direction shown in the figure while no current flows between C and B because current is cut off by the diode D2. Contrary to the aforementioned, if the voltage in C is higher than that in A, current flows in the direction as shown in the figure, with no current flowing between A and B. This is because the diode D1 cuts off the current between A and B. As a result, voltage generated between the DC terminals has a waveform with two peaks in one cycle, as in the case of the output waveform shown in Fig. 5-9.
5-4 ELECTRONIC IGNITION SYSTEM

The electronic ignition system features a power transistor as the current control element. Therefore, the ignition system is an electronic contact point-free type that operates with the power transistor impulses controlling the current. This system is also called TIC (transistor igniter circuit) and is virtually free of ignition failure which generally results from contamination of the contact points, a typical problem with contact type ignition systems.

Because this ignition system has no contact points, it is not affected by moisture, oil, dust, or other contaminants. As a result, this electronic ignition system ensures sure and positive ignition with reduced maintenance. The TIC mechanism consists of a transistor-incorporated ignition coil and a permanent magneto built-in flywheel which is press-fitted on the rotor shaft of the generator.

![Diagram of Electronic Ignition System]

(1) When the permanent magneto built-in flywheel starts rotating, power is generated in the primary coil of the ignition coil and current flows to the resistor (a). From the resistor, current flows to the power transistor. With this current, the power transistor turns on, releasing current (b). This stage corresponds to the closing of contact points.

(2) As the flywheel comes to the point of ignition, the ignition timing detecting circuit is activated while the current (c) is flowing through the circuit. When the ignition timing detecting circuit is activated, the signal transmitter transistor actuates with current (d) flowing. When current (d) starts flowing, current (b) flowing through the power transistor is cut quickly. As a result, high voltage is produced in the secondary coil and this voltage is applied simultaneously to the spark plug which ignites for ignition. This stage corresponds to the opening of contact points.
6. SAFETY PRECAUTIONS

1. Use extreme caution near gasoline. A constant danger of explosion or fire exists.
   Do not fill the fuel tank with gasoline while the engine is running. Do not smoke or use open flame near the fuel tank. Be careful not to spill fuel when refueling. If spilt, wipe it and let it dry before starting the engine.

2. Do not place inflammable materials near the generator.
   • Be careful not to put gasoline, matches, gunpowder, oil cloth, straw, trash and any other inflammables near the generator.
   • Operate the generator at least 1 meter (4 feet) away from a building or wall.

3. Do not operate the generator in a room, cave or tunnel. Always operate in a well-ventilated area.
   Otherwise the engine may become overheated and also, the poisonous carbon monoxide contained in the exhaust gases will endanger human lives. Keep the generator at least 1 m (4 feet) away from structures or facilities during use, and always operate it with the exhaust pipe directed toward the open-air or where good ventilation is assured.

4. Operate the generator on a level surface.
   • Do not operate the generator on a inclined surface.
   • Do not move or carry the generator while it is running.

5. Do not operate with wet hands or in the rain.
   Severe electric shock may occur. If the generator is moistened by rain or snow, wipe it and fully dry it before starting.
   • Do not pour water over the generator directly nor wash it with water.
   If the generator is wet with water, the insulations will be adversely affected and may cause current leakage and electric shock.

6. Do not connect the generator to the residential power source.
   This could result in a malfunction of, or damage to the generator or appliance to which it is connected or could even lead to fire.

7. Do not cover the generator with a carton, a box or other cover while it is running.
7. RANGE OF APPLICATIONS

7-1 AC OUTPUT

Generally, the rated power of an electrical appliance often refers to the amount of work that can be done by it. The electric power required for operating an electrical appliance is not always equal to the amount of work that can be done by it. Electrical appliances generally have a label showing their rated voltage, frequency, and power consumption (input power). The power consumption of an electrical appliance is the power necessary for using it. When using a generator for operating an electrical appliance, however, the power factor and starting current must also be taken into consideration.

Determine the capacity of your generator from the power required for operating electrical appliances referring to the followings:

(1) **Incandescent lamps, hot plates, etc. with a power factor 1.0**

Total power consumption must be equal to or less than the rated output of generator.

Example: A generator with a rated output power of 500W can light five 100W lamps.

(2) **Fluorescent lamps, mercury lamps, etc. with a smaller power factor**

Select a generator with a rated output equivalent to 1.2 to 2 times the power consumption of the load.

Example: A generator with a capacity of 100W to 160W is necessary for lighting a 80W fluorescent lamp. A generator with a rated output of 500W can light three to five 40W fluorescent lamps.

**NOTE:** Wattage of the fluorescent lamp generally does not indicate the power consumption but indicates the output of the lamp. Therefore, if the fluorescent lamp has no special indication as to the power consumption of input power, efficiency should be taken into accounts as explained in Item 5 on the following page.

(3) **Electric tools, etc. that are driven by a motor**

1.2 to 3 times large power consumption of a motor-driven tool is required for starting. Select a generator with a maximum output 1.2 to 3 times large to the load.

Example: A 300W motor-driven drill requires a generator with a maximum output of 400 to 900W or more.

(4) **Water pumps, compressors, etc. that are driven by a motor and are initially loaded**

3 to 5 times large power is necessary for starting. Select a generator with 3 to 5 times large output of load.

Example: A water pump with a power consumption of 400W requires a generator with a maximum output of 1200 to 2000W or more.

**NOTE 1:** Motor-driven appliances mentioned in Items 3 and 4 required the aforementioned generator capacities only when starting their motors. Once their motors are started, the appliances consume about 1.2 to 2 times their rated power consumption so that the excess power generated by the generator can be used for other electrical appliances.

**NOTE 2:** Motor-driven appliances mentioned in Items 3 and 4 vary in their required motor starting power depending on the kind of motor and start-up load. If it is difficult to determine the optimum generator capacity, select a generator with a larger capacity.
Appliances without any indication as to power consumption

Some appliances have no indication as to power consumption; but instead the work load (output) is indicated. In such a case, power consumption is to be worked out according to the numerical formula mentioned below.

\[
\frac{\text{Output of electrical appliance}}{\text{Efficiency}} = \text{Power consumption}
\]

Efficiencies of some electrical appliances are as follows:

- Single-phase motor ............... 0.6 ~ 0.75 —— The smaller the motor, the lower
- Three-phase motor ............... 0.65 ~ 0.9 —— the efficiency.
- Fluorescent lamp ................. 0.7 ~ 0.8

Example 1: A 40W fluorescent lamp means that its luminous output is 40W. Its efficiency is 0.7 and accordingly, power consumption will be \(40 \div 0.7 = 57W\). As explained in Item 2, multiply this power consumption value of 57W by 1.2 ~ 2 and you will get the figure of the necessary capacity of a generator. In other words, a generator with a rated output of 500W capacity can light four to seven 40W fluorescent lamps.

Example 2: Generally speaking, a 400W motor means that its work load is 400W. Efficiency of this motor is 0.7 and power consumption will be \(400 \div 0.7 = 570W\). When this motor is used for a motor-driven tool, the capacity of the generator should be multiplied by 1.2 to 3 and 570W as explained in the Item 3.

Table 7-1

NOTES: Wiring between generator and electrical appliances

1. Allowable current of cable
   Use a cable with an allowable current that is higher than the rated input current of the load (electrical appliance). If the input current is higher than the allowable current of the cable used, the cable will become excessively heated and deteriorate the insulation, possibly burning it out.
   Table 7-2 shows cables and their allowable current for your reference.

2. Cable length
   If a long cable is used, a voltage drop occurs due to the increased resistance in the conductors so that the input voltage to the load (electrical product) decreases. As a result, the load can be damaged.
   Table 7-2 shows voltage drops per 100 meters of cable.
Voltage decrease indicates as $V = \frac{1}{100} \times R \times I \times \ell$

$R$ means resistance ($\Omega/100$ m) on the above table.
$I$ means electric current through the wire (A).
$\ell$ means the length of the wire (m).

The length of the wire indicates round length, it means twice the length from generator to electrical tools.

### 7-2 DC OUTPUT

When the generator is employed to recharge batteries, care must be exercised about the specific gravity of electrolyte in each battery case.

#### 7-2-1 MEASURING THE SPECIFIC GRAVITY OF ELECTROLYTE:

The specific gravity changes with temperature; therefore, it is converted to another, corresponding to 20°C.

$$S_{20} = S_t + 0.0007 \ (t - 20)$$

where

- $S_{20}$ = Specific gravity corresponding to 20°C
- $S_t$ = Measured value
- $t$ = Temperature at time of measurement

#### 7-2-2 REMAINING CAPACITY ESTIMATED WITH REFERENCE TO THE SPECIFIC GRAVITY OF ELECTROLYTE:

7.2.3 BATTERY CAPACITY
The battery capacity is expressed in units of ampere-hour (AH). One AH stands for the capacity capable of providing one ampere of current for one hour.

7.2.4 SIMULTANEOUS USE OF THE AC/DC OUTPUT
If you use the AC/DC output simultaneously in this generator, be careful not to exceed the total power consumption.

- 50 Hz ___________ below 250W
- 60 Hz ___________ below 350W

NOTE: Max. output of DC is 100W (12V x 8.3A).
8. MEASURING PROCEDURES

8-1 MEASURING INSTRUMENTS

8-1-1 VOLTMETER
AC voltmeter is necessary. The approximate AC voltage ranges of the voltmeters to be used for various types of generators are as follows:
0 to 150V: Type with an output voltage of 110V or 120V
0 to 300V: Type with an output voltage of 220V, 230V or 240V

8-1-2 AMMETERS
AC ammeter is necessary. An AC ammeter with a range that can be changed according to the current rating of a given generator is most desirable. (About 10A, 20A, 100A)
Prepare a DC ammeter which has a scale range of 15A.

8-1-3 FREQUENCY METER
Frequency range: About 45 to 65 Hz.
NOTE: Be careful of the frequency meter's input voltage range.
**8-1-4 CIRCUIT TESTER**
Used for measuring resistance, etc.

![Circuit Tester Image](Fig. 8-4)

**8-1-5 MEGGER METER**
Used for measuring generator insulation resistance. Select one with testing voltage range of 500V.

![Megger Meter Image](Fig. 8-5)

**8-1-6 TACHOMETER**
Use a contact-less type tachometer.

![Tachometer Image](Fig. 8-6)
8-2 MEASURING AC OUTPUT

With the circuit shown in Fig. 8-7, measurement is made of the AC output of the generator. An electric heater or an incandescent lamp with a power factor of 1.0 is suitable as a load for the generator. When the measured AC output of the generator is confirmed to be within the voltage range specified in the table below, over its voltage rating, the AC output is normal. Measurement must be made under rated load and at rated speed; sometimes, load and speed adjustments are necessary.

<table>
<thead>
<tr>
<th>Voltage rating</th>
<th>110V</th>
<th>120V</th>
<th>220V</th>
<th>240V</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range of voltage</td>
<td>104 ~ 107V</td>
<td>114 ~ 127V</td>
<td>211 ~ 234V</td>
<td>227 ~ 253V</td>
</tr>
</tbody>
</table>

Table 8-1

8-3 MEASURING DC OUTPUT

Measurement is made of the DC output of the generator with the switch shown in the above circuit turned on while the generator is kept running at its rated speed. The DC output should be within 11 to 14 with the current regulated at 8.3A by adjusting the load connected to the generator.

*NOTE: If a battery is connected as a load to the generator, the DC output voltage will increase by approximately 1 to 2V. Therefore, carefully observe the electrolyte level and do not overcharge the battery.*

8-4 MEASURING INSULATION RESISTANCE

To measure insulation resistance, connect the megger tester across either one of the two output terminals of the socket and the earth terminal. When the measured insulation resistance of the generator is over 1 MΩ, it is normal (over 10MΩ at time of shipment).

(Be sure to turn on the circuit breaker when measuring insulation resistance.)

If the insulation resistance is less than 1MΩ, disassemble the generator, and measure the respective resistances of the stator, rotor and control panel.
8-4-1 STATOR
Measure the insulation resistance between the RED lead and the core.
The resistance should be larger than 1 MΩ.
If the resistance is less than 1 MΩ, the insulation is failed. Replace the stator with a new one.

8-4-2 ROTOR
Measure the insulation resistance across one of the soldered terminals of the rotor and the core.
The resistance should be larger than 1 MΩ.
If the resistance is less than 1 MΩ, the insulation is failed. Replace the rotor with a new one.

8-4-3 CONTROL PANEL
Measure the insulation resistance between the live parts and the grounded part.
If the measured resistance of a component is below 1 MΩ, the insulation is defective.
Promptly replace the defective component because there may be leakage of current from the generator and a potential danger of electrical shock.
9. CHECKING FUNCTIONAL MEMBERS

9-1 CONTROL PANEL

9-1-1 ENGINE SWITCH

Using a circuit tester, check continuity across the black and green top terminals of the 6P coupler. When continuity between the terminals is confirmed with the engine switch turned off, the switch is normal. It is also normal if there is no continuity between these terminals, when the engine switch is set at RUN or CHOKE position.

Fig. 9-1

9-1-2 VOLTMETER

Also check with the circuit tester, the continuity across the white and brown top terminals of the 6P coupler. If continuity is confirmed between these terminals, the voltmeter is normal.

Fig. 9-2

9-1-3 PILOT LAMP

Check the pilot lamp to be turned on by applying specified voltage. Pilot lamp cannot be checked with a circuit tester because it is a light emitting diode and its resistance is too large.
9-1-4 AC RECEPTACLES
Using a circuit tester, check continuity between the two terminals at the rear of the AC receptacles while the receptacle is mounted on the control panel. When continuity is confirmed between the output terminals of the receptacle with a wire connected across these terminals, the AC receptacle is normal. When the wire is removed and no continuity is confirmed between these terminals, the receptacles are also normal.

\[\text{Fig. 9-3 (A)}\]

9-1-5 DC TERMINALS
Using a circuit tester, check continuity between the DC terminals at the rear side of the control panel while they are mounted on the panel. When continuity is confirmed between the DC terminals with a wire connected across these terminals, the DC terminals are normal. When the wire is removed and no continuity is confirmed between these terminals, the terminals are also normal.

\[\text{Fig. 9-4}\]

9-1-6 CIRCUIT BREAKER
Check continuity between each of two terminals at the rear of the circuit breaker while it is mounted on the control panel. Normally, there is continuity between each of the two when the circuit breaker is on while there is no continuity when the circuit breaker is off.

[6P COUPLER WIRING]

\[\text{Fig. 9-5}\]
# 9-2 STATOR

Measure the resistance of each stator coil using the circuit tester.

\[(R \times 1\Omega \pm 10\%)\]

**Table 9-1**

*NOTE: If the circuit tester is not sufficiently accurate, it may not show the values given and may give erroneous readings.*

**[6P COUPLER WIRING]**

![6P Coupler Wiring Diagram]

**[3P COUPLER WIRING]**

![3P Coupler Wiring Diagram]
9-3 ROTOR

1) Unsolder the diode and the resistor from the rotor terminal.
   Unsolder one wire of each part.

2) Check the resistance between the wire ends of rotor winding at the terminals.

<table>
<thead>
<tr>
<th>NORMAL RESISTANCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.5Ω</td>
</tr>
</tbody>
</table>

3) Check the diode.
   Touch the positive (RED) probe of the circuit tester to the cathode mark side of the diode, and
   touch the negative (BLACK) probe to the other side of the diode. Normal resistance is 16Ω.
   Reverse the polarity of the circuit tester.
   At this time, the resistance is infinity.
   [Remedy]
   If the diode is defective, replace with a new one.
9-4 IGNITION COIL

Using a circuit tester, measure the resistance of the ignition coil.

<table>
<thead>

</tr>
</tbody>
</table>

*Table 9-2*

9-5 CONDENSER

If an instrument (QC-meter or C-meter) for measuring the capacity of a condenser is available, check the capacity of the condenser.

<table>
<thead>
<tr>
<th>NORMAL CAPACITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 ~ 11μF</td>
</tr>
</tbody>
</table>

Usually the instrument is expensive and difficult to obtain, we suggest instead that you install a new condenser and see if the generator works. If the generator works with a new condenser, the old one is defective.

9-6 DIODE RECTIFIER

Using a circuit tester, measure the resistance between each of the two terminals of the rectifier. The rectifier is considered normal when the respective resistances have the values specified below.

10. DISASSEMBLY AND ASSEMBLY

10-1 PREPARATION AND PRECAUTIONS

1) Be sure to remember the locations of individual parts when disassembling the generator so that the generator can be reassembled correctly. Tie tags noted with the necessary information to facilitate easier and smoother reassembly.

2) For more convenience, divide the parts into several groups and store them in boxes.

3) To prevent bolts and nuts from being misplaced or installed incorrectly, place them temporarily back at their original position.

4) Handle disassembled parts with care; clean them before reassembly using a neutral cleaning fluid.

5) Use all disassembly/assembly tools properly, and use the right tool for each specific job.

6) Drain fuel tank of fuel and crankcase of oil before disassembly.

10-4 ASSEMBLY PROCEDURE

10-4-1 PRECAUTION IN ASSEMBLY

(1) Thoroughly clean each part. When cleaning, take special care for the piston, cylinder, crankshaft, connecting rod, and bearing.

(2) Be sure to completely remove the carbon deposits on the cylinder head and piston head. Also, thoroughly clean and remove carbon deposits from each piston ring groove.

(3) Apply lubricating oil to the lip of each seal. Confirm that the lip of each oil seal is not damaged. If damaged, replace with a new one.

(4) Replace the gaskets and similar items with new ones; do not reuse old gaskets.

(5) Replace the keys, pins, bolts, nuts, etc. with new ones if necessary.

(6) Do not apply torque exceeding the specified value.

(7) Apply lubricating oil to both moving and sliding parts when they are assembled.

(8) Prior to assembly, check the clearance of each part, and adjust it if necessary.

(9) When each of the main components are assembled, turn it by hand to check for smoothness of rotation and unusual noise.

10-4-2 ASSEMBLY SEQUENCE AND PRECAUTIONS

(1) GOVERNOR SHAFT
Put the governor shaft into crankcase, then drive the clip into position to secure the governor shaft.

(2) CRANKSHAFT
a) Insert the crankshaft into the ball bearings of the crankcase.

b) Fig. 10-13 shows the dimensional tolerance of the crankpin.
• TOLERANCE OF NEWLY INSTALLED PARTS

| Clearance of piston ring joint | Top ring | 0.2L ~ 0.4L | Second ring | 0.2L ~ 0.4L | Oil ring | 0.05L ~ 0.25L | Spare rings |
| Clearances between piston ring | Top ring | 0.090L ~ 0.135L | Second ring | 0.060L ~ 0.105L | Oil ring | 0.010L ~ 0.065L |
| Clearances between connecting rod large end and crankpin | Inside and outside diameter clearance | 0.037L ~ 0.063L | Side clearance | 0.1L ~ 0.7L |
| Clearances between connecting rod small end and piston pin | 0.010L ~ 0.029L |
| Clearances between piston pin and piston pin hole | 0.009T ~ 0.010L |

Table 10-2

NOTE: The clearance between the piston and cylinder is checked by measuring the clearance between the piston and cylinder skirt.

(3) PISTON and PISTON RINGS

a) If a ring expander is not available, set the ring joint at the first land of the piston, as shown in Fig. 10-14 so that the ring can be slided into its groove.

NOTE: Be careful not to twist or expand excessively each ring. The oil ring is fitted first on to the piston, followed by the second ring and top ring.

The top and second rings must be fitted with their marked sides kept upward.

b) The connecting rod is assembled to the piston by the piston pin.

NOTE: Before assembly, apply sufficient lubricating oil to the connecting rod small end.

NOTE: Be sure to fit the clips to both sides of the piston pin.
(4) INSTALLING THE CRANKCASE
The connecting rod is put into the cylinder while holding it with the piston ring guide, as shown in Fig. 10-16 (in the case that a piston ring guide is not available, press rings inward with fingers and at the same time, strike down the piston, using a wooden block). The connecting rod must be mounted in place with its θ and MA marks directed to the ball bearing side of the crankcase.

NOTE: Apply a sufficient quantity of oil to the piston rings, connecting rod surfaces, and cylinder.

NOTE: The top, second and oil rings are fitted to the piston with their ring joints arranged 90° off each adjacent joint.

(5) INSTALLING THE CONNECTING ROD MAJOR END CAP

a) Manually turn the crankshaft until the piston reaches top dead center. Gently strike down the piston head until the connecting rod touches the crankpin to install the connecting rod major end cap.

b) The cap is installed with the oil scraper positioned right-downward. (See Fig. 10-17.)

NOTE: Be sure to use a new lock washer; and carefully bend the washer correctly.

NOTE: When the cap has been installed, turn the crankshaft to see if the connecting rod moves smoothly.

NOTE: The correct torque for installing the connecting rod major end cap is 60 to 80 kg-cm.

NOTE: See Table 10-2 for details regarding the clearances between the piston, piston rings, and connecting rod and their counterparts.

(6) INSTALLING THE TAPPETS AND CAMSHAFT
Install the tappets, and then the camshaft.

NOTE: Align the timing mark at the base of the cam gear with the timing mark of the crank gear. If the valve timing is set incorrectly, the engine will not run or operate properly. (See Fig. 10-18.)

NOTE: If the intake and exhaust valves are installed in reverse order, tappet clearance will be incorrect.
(7) INSTALLING THE MAIN BEARING COVER

Install the main bearing cover to the crankcase.

NOTE: The governor gear is already mounted to the bearing cover; therefore, it is necessary to confirm that the governor gear is meshed with the cam gear. (See Fig. 10-19.)

If the oil seal requires replacement, press-fit the new oil seal in position before installing the main bearing cover.

NOTE: Prior to installation, apply oil to the bearing and oil seal. Apply a small amount of oil to the cover fitting face, as specified, in preparation for installing the bearing cover packing. Place the oil seal guide over the crankshaft so that the oil seal lip will not be damaged during installation. Make sure the side clearance of the crankshaft is within 0 to 0.2 mm. If necessary, adjust the clearance, using the adjusting collar. (See Fig. 10-20.)

NOTE: Torque for the main bearing cover: 80 ~ 100 kg-cm.

*Shown in Fig. 10-21 is the method to measure the side clearance of the crankshaft. According to this method, measure the clearance between the machined face of the crankcase and the adjusting collar. The machined face of the crankcase is mounted with packing so it is necessary to set the clearance properly by allowing for a packing thickness of 0.22 mm.

M6 x 25 mm bolt ............ 8 pcs.
M6 x 55 mm bolt ............ 1 pc.
(8) INSTALLING THE INTAKE AND EXHAUST VALVES

Prior to installing, remove carbon and gum deposits from the valve, valve seat, intake and exhaust ports, and valve guide.

**NOTE:** If the valve face is worn, replace the valve with a new one.

**NOTE:** If the clearance between the valve guide and valve stem is excessively large, replace the valve guide with a new one.

Replace the valve guide by using a pull block and pull bolt as shown in Fig. 10-23.

![Fig. 10-22](image)

Table 10-3

L: LOOSE
(9) TAPPET ADJUSTMENT

Set the tappet at the lowest position to depress the valve. Then measure the clearance between the valve and tappet stem, using a clearance gauge inserted into the clearance. (See Fig. 10-24.)

**NOTE:** As with the intake and exhaust valves, the clearance between the valve and tappet stem must be 0.08 ~ 0.12 mm.

![Fig. 10-24](image)

**NOTE:** If the clearance is smaller than that specified, slightly grind down the valve stem end using a grinder, then measure the clearance.

If the clearance is larger than that specified, replace the valve with a new one. Spot the valve seat and use some compound to adjust the clearance.

**NOTE:** After completing adjustment of tappet clearance, install the valve spring retainers, and then recheck the tappet clearance.

- Installing the valve spring retainer
  Using the special tool, place the retainer over the valve stem with the notch in the outside periphery of the retainer kept toward the front.

(10) INSTALLING THE CYLINDER HEAD

Before reinstalling the cylinder head, be sure to remove carbon deposits from the combustion chamber, and clean between the cooling fins. Also check the cylinder head for levelness.

**NOTE:** Replace the cylinder head gasket with a new one.

The cylinder head is installed using seven M6 x 32 mm bolts.

**NOTE:** Torque for each cylinder head bolt: 90 ~ 110 kg-cm

(11) INSTALLING THE SPARK PLUG

Torque for spark plug: 120 ~ 150 kg-cm

(12) INSTALLING THE CYLINDER BAFFLE

The cylinder baffle is installed to the crankcase, using the M6 x 20 mm screw and to the main bearing cover, using the M5 x 10 mm screw.

The cylinder baffle and fuel line clamp are installed together to the crankcase.
(13) INSTALLING THE HEAD COVER

The head cover is installed over each of the left and right parts of the cylinder head, using the M5 x 10 mm screws.

(14) INSTALLING THE GOVERNOR AND RELATED PARTS

Model EY08D has a centrifugal weight type governor which is installed while engaged with the governor gear. With the governor, the throttle valve of the carburetor is controlled automatically by using a lever link mechanism. Therefore, engine speed is constantly maintained even under load variations.

a) Using two M6 x 12 mm bolts, install the speed control assembly to the crankcase.
b) Temporarily install the carburetor with two M6 flange nuts.
c) Join the throttle lever and governor lever of the carburetor to the governor rod and rod spring.
d) Insert the governor lever into the governor shaft.
e) Insert a minus screwdriver into the groove of the governor shaft, and turn the screwdriver fully in the clockwise direction. Push the governor lever clockwise (at this time, the throttle valve is fully opened) and fasten the governor lever with the lock bolt.

Torque for the governor lever: 70 ~ 90 kg-cm

Link the governor lever and speed controller with the governor spring, one of which is inserted into the center hole (of the three) of the governor lever and the remaining end inserted into the hole of the speed controller.
(15) INSTALLING THE CARBURETOR AND AIR CLEANER

Place the carburetor gasket, insulator, gasket, and carburetor in the correct positions. Next, fit the air cleaner gasket and air cleaner case, and install them, using the M6 nut and M5 x 10 mm screw. Set the element (small type), element retainer, element and cleaner cover, and tighten them with screws (slot head type).

Torque for installing carburetor: 90 ~ 100 kg-cm

NOTE: See page 59 for details concerning disassembly and assembly of the carburetor.

(16) INSTALLING THE CENTER BAFFLE AND FRONT HOUSING

Set the dowel pin hole of the front housing to the dowel pin of the main bearing cover and assemble them together. During assembly, place the center baffle between the main bearing cover and front housing.

Torque for the front housing: 80 ~ 100 kg-cm

(17) INSTALLING THE IGNITION COIL

a) Install the ignition coil and grommet (IG-COIL) to the front housing. Simultaneously, set temporarily the generator rotor in position. And assemble the ignition coil and magnet together while adjusting the air gap between the two to 0.4 to 0.5 mm.

Firmly bond the grommet to the front housing ensuring that there is no residual clearance. (Use CEME-DINE 575).

b) Fit the plug cap on the spark plug.

(18) INSTALLING THE ROTOR ASSEMBLY

Install the rotor assembly to the taper of the crankshaft with their keyways in line.

NOTE: Thoroughly clean the tapers (both male and female tapers) of oil or grease before assembly.

(19) INSTALLING THE STATOR ASSEMBLY

a) Install the stator correctly into the recess of the rear housing. Note the leads and their positions.

b) Install the wiring between the stator and rear housing. Connect the wires from the stator to the condenser (with these wires joined to two black top terminals). Also connect the wires from the stator to the rectifier (with these wires joined to three terminals.)

Connect the ground cord to the rear housing, using one M6 x 8 mm screw.

c) Install the stator assembly correctly into the recess of the front housing. If necessary, strike softly the rear housing with a plastic hammer (be careful not to strike the condenser and rectifier).

d) Fasten the front housing to the rear housing of the stator assembly, using three M6 bolts, while the three bosses of the front housing are set to their counterparts of the rear housing.

Torque for each bolt: 65 ±10 kg-cm

e) Clamp the lead of the 6P coupler and the lead from the ignition coil to the bolts specified in paragraph d), using wire bands.

(20) INSTALLING RUBBER MOUNT (A)

a) Fit rubber mount (A) to the bosses (two) at the lower center of the crankcase.

b) Also fit another rubber mount (A) to the bosses at the lower part of the stator assembly of the generator.
(21) INSTALLING THE STARTER PULLEY
Install the starter pulley to the rotor shaft using the rotor through bolt. Torque for the through bolt: 100 ~ 150 kg-cm

(22) INSTALLING THE RECOIL STARTER
Install the recoil starter to the rear housing using the M6 flange bolt.

(23) RUBBER TUBE FOR BREATHER
Connect rubber tube to the air vent joint of the carburetor. Keep this rubber tube suspended downward from the air vent joint.

(24) INSTALLING THE BASE FRAME
a) Install the base frame with its rear side facing the welded nut area of rubber mount (A). Match the rubber mount (A) which is fitted to the lower part of the engine and generator. Base plate is installed using four M5 bolts.
b) Insert rubber tube from the air vent joint of the carburetor into the hole in the base frame.
c) Fasten the ground terminal to the rear housing using M6 bolt.

(25) INSTALLING THE MUFFLER AND MUFFLER COVER
a) Fit the gasket (for the muffler cover) to the studs of the exhaust flange of the crankcase.
b) Using M5 screws, install the muffler cover in place.
   Note: Be careful not to drop the screws into the cooling air channel.
c) Set the gasket (for the exhaust port) on the studs of the exhaust port flange. Then, mount the asbestos to the upper and lateral sides of the muffler. The muffler is installed while secured to the muffler flange using two M6 nuts, and also to the muffler bracket by using one M6 bolt.
d) Install the outer muffler cover in place using seven M5 tapping screws.
   Torque: 70 ~ 90 kg-cm

(26) INSTALLING THE CHOKE CABLE
a) Insert the inner wire of the choke cable into the swivel of the choke lever.
b) Insert the outer end of the choke cable into the wire bracket of the carburetor, and temporarily tighten the outer end so that it will not slip out of the wire bracket.
   NOTE: The inner wire is installed later. Leave it loose in the swivel.

(27) INSTALLING THE FUEL LINE
a) Connect the fuel line to the inlet joint of the carburetor. Then, clamp the line with a hose clamp so that it will not come off the line joint.
b) Secure the fuel line with the clamp of the cylinder baffle.
(28) INSTALLING THE FRONT COVER

Using two M6 x 8 mm flange bolts, install the front cover assembled with the control panel to the base plate. Keep the engine switch set at STOP.

(29) INSTALLING THE FUEL TANK

a) Keep the strainer shaft at the lower part of the fuel tank in a position that will allow the setscrews to be tightened from the opposite direction of the muffler.
b) Insert the flexible shaft extending from the rear side of the engine switch which is mounted on the control panel into the square hole of the strainer shaft.
c) Align the mounting holes at the lateral side of the front cover with those in the bracket which are bolted to the fuel tank. Then, install the fuel tank, using two M6 x 8mm flange bolts.
d) Make sure that the flexible shaft on the control dial side is inserted in the square hole of the strainer shaft, then fasten the flexible shaft.

(30) INSTALLING THE REAR COVER

Align the mounting holes at the lateral side of the rear cover with those in the fuel tank bracket. Then install the rear cover, using two M6 x 8 mm flange bolts. Also align the holes at the lower part of the rear cover with those in the base plate, and install the rear cover by two M6 x 8 mm flange bolts.

NOTE: Pull out the fuel drain pipe of the carburetor through the hole on the rear cover. The frequency changeover switch knob have to be drawn out through the rubber shield.

(31) INSTALLING THE FUEL TANK HANDLE

a) Set the bolt (to secure the tank handle) in the handle and assemble the O-ring to this bolt from the opposite side. Then, tighten the bolt to install the handle to the fuel tank.

NOTE: Be sure to direct the less slanted part of the handle toward the front cover.
b) Insert the rubber tube end over the protrusion of the bolt (for the fuel tank) and push it down to the base of the protrusion.

NOTE: Be sure to keep the air breathe hole at the center of the rubber tube directed upward.
c) Place the handle cover over the handle.

(32) INSTALLING THE FUEL LINE

Insert the fuel line end over the fuel strainer joint (be sure to push the line end down to the joint base), and secure it with the clamp.

(33) INSTALLING THE CHOKE CABLE

a) Insert the choke cable adjusting screw in its hole on the fuel tank bracket.
b) Secure this adjusting screw with the M6 nut and tighten to the midway point of the threaded part.
c) Set the dial of the control panel to STOP, and connect the choke cable end to the lever of the panel.
d) Pull the inner wire of the choke cable to clamp the wire to the choke-lever, using the setscrew.

(34) CONNECTING THE COUPLERS TOGETHER

Connect the coupler (6P) from the generator to the coupler (6P) extending from the control panel. Also connect the stop wire (green) as required.
(35) INSTALLING THE LEFT SIDE COVER
Pull out the starter handle through the cover and install the left side cover to the generator with four M5 flange screws.

(36) INSTALLING THE RIGHT SIDE COVER
Fit the foam rubber stuck inside of the right side cover to the air outlet window of the muffler cover, and install the cover to the generator with four M5 flange screws.
10-5 CARBURETOR

10-5-1 FUNCTION AND COMPONENTS (See Fig. 10-32)

(1) FLOAT SYSTEM

The float chamber is located directly under the carburetor. Float and needle valve maintain a constant fuel level inside the float chamber. The fuel in the tank flows into the float chamber from the needle valve. When a certain quantity of fuel enters the chamber, the float rises. When the buoyancy of the float balances with the fuel pressure at the needle valves, the valve closes to keep the fuel at the correct level.

SCHEMATIC DIAGRAM OF THE FUEL SYSTEM

Fig. 10-32
(2) PILOT JET NOZZLE SYSTEM
The pilot jet nozzle system controls the fuel supply for engine speeds ranging from idle to low-speed running. The system operates with the fuel flowing through the main jet nozzle and up to the pilot jet nozzle where the fuel is measured. When the fuel is mixed with air, the volume of the air-fuel mixture is also measured by the pilot air jet. From this stage, the mixture is supplied to the engine from the pilot outlet and bypass. During idle, fuel is supplied mainly from the pilot outlet.

(3) MAIN JET NOZZLE SYSTEM
The main jet nozzle system supplies fuel for middle and high speed operation. The fuel flows to the main jet nozzle where the fuel quantity is measured, and then flows to the main nozzle. Air volume, which is measured by the main air jet, enters from the breath hole of the main nozzle and mixes with fuel to form a gas mist. The gas mist flows out of the main bore and is again mixed with air from the air cleaner. From this stage, the correct air-fuel mixture is supplied to the engine.

(4) CHOKE
The choke helps in starting the engine in cold weather. When the engine is started with the choke valve closed, negative pressure applied to the main nozzle rises, allowing most of fuel to flow through the main nozzle. A mixture with a high gasoline concentration is fed to the engine resulting in easier engine starting.

10-5-2 DISASSEMBLY AND ASSEMBLY OF CARBURETOR
The most common trouble with the carburetor is failure to provide the correct air-fuel mixture. This is generally caused by blockage in the air and fuel passages, at other times it is caused by fuel level fluctuations in the float chamber. In order to maintain the carburetor in normal operating condition, it is vital that the air and fuel passages be kept clean. The following descriptions are the procedures for carburetor disassembly and assembly. (See Fig. 10-33.)

(1) THROTTLE MECHANISM
a) Remove Philips-head screw (27), throttle valve (28), and pull out the throttle shaft (29).
b) When removing the throttle stop screw, a spring (31) will also come off. Be careful when handling the throttle valve to prevent the valve edge from damage.

(2) CHOKE
a) Remove Philips-head screw (22), choke valve (23), and pull out choke shaft (24).
b) Be sure to keep the notch of the choke valve positioned forward the main air jet side when the choke shaft is installed.

(3) PILOT JET NOZZLE
a) Remove pilot jet nozzle (21). When removing, use a proper tool so that the nozzle will not be damaged.
b) Firmly secure the jet nozzle when the carburetor is assembled. Otherwise, fuel will leak from the nozzle and cause engine trouble.

(4) MAIN JET NOZZLE
a) Remove bolt (19), and float chamber body (13).
b) Remove main jet nozzle (19) from carburetor body (9).
c) Firmly secure the main jet nozzle when assembling. Otherwise, air-fuel mixture will become excessively rich and the engine will not operate properly.
d) Torque for bolt (15) is 70 kg-cm.
(5) FLOAT SYSTEM

Pull out float pin (12) and remove float (11) and needle valve (20).

- Avoid using a drill or a wire to clean the fuel passages (they may damage the orifice of the pilot and main jet nozzles). Use compressed air.
- The float pin is peen-secured to the carburetor body; the needle valve and float can be removed out from the opposite side of the peen-secured part by lightly striking the float pin with a thin bar-like object.

Fig. 10-33
10-6 FREQUENCY CHANGEOVER SYSTEM (50 Hz/60 Hz Selectable Type)

10-6-1 CONSTRUCTION AND FUNCTION

When the control lever (13) is turned to upper position, the lever (12) is pulled back by the governor spring (10) to decrease the spring force of the governor spring to set the engine speed at 3,000 rpm (50 Hz). At the same time, the cam (14) combined with the control lever (13) releases the micro-switches (18) to switch the circuits in the condenser coil and the main coil from 60 Hz to 50 Hz.

When the control lever (13) is turned to lower position, the adjusting screw (22) on the control lever pushes the lever (12) to pull the governor spring (10) increasing the spring force to set the engine speed at 3,600 rpm (60 Hz).

At the same the cam (14) pushes the micro-switches (18) to switch the circuit from 50 Hz to 60 Hz.

The frequency of the output electricity can be adjusted by turning the adjusting screws (22) for 60 Hz or the screw (21) for 50 Hz.

Fig. 10-34
10-6.2 DISASSEMBLY

1) Unhook the spring (16) and remove the control lever (13) with knob (15).
2) Remove the clip (9) to disassemble the lever (12) and cam (14).
3) Remove two screws (19) to detach the micro-switches (18).
11. TROUBLESHOOTING

In troubleshooting the generator, you will encounter certain categories of problems. It is important to check each component step by step. You will certainly find the cause of any trouble through a systematic Troubleshooting.

11-1 ENGINE DOES NOT START OR ENGINE DOES NOT RUN NORMALLY.

11-1-1 CHECK THE BASICS

1) The control switch should be in the “CHOKE” position. If the engine has already been warmed up, the control switch should be in the “RUN” position.
2) There should be sufficient gasoline in the fuel tank.
3) The spark plug cap should fit snugly on the spark plug.
4) All electric appliances should either be disconnected from the generator or their switches should be turned off. A generator often will not start if a load is already turned “ON” at starting.

11-1-2 CHECK THE IGNITION SYSTEM

(1) CHECKING SPARK AT SPARK PLUG

- Open the spark plug cover and remove the plug cap.
- Remove the spark plug and check to see that it is clean and has an adequate plug gap. Use the correct spark plug, NGK BMR4A or CHAMPION PCJ8.
  Keep the plug gap between 0.6 ~ 0.7 mm (0.02 ~ 0.03 in.).
- Insert the spark plug into the plug cap.
- Ground the metal body of the spark plug against the metal part of the generator.
- Set the control switch in the “RUN” position, pull the starter handle and check the spark. If the spark is strong, the ignition system is normal. If the spark is weak, or if there is no spark at all, the ignition system is defective.

(2) CHECKING IGNITION COIL

If a strong spark is not produced at spark plug, the next step is to check the ignition coil.

- Remove the side covers left and right.
- Remove the muffler cover, muffler and the inner muffler cover.
- Using a circuit tester, check the resistance between the green wire and the core of the ignition coil.

<table>
<thead>
<tr>
<th>NORMAL RESISTANCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>HIGH-TENSION CORD—GREEN WIRE</td>
</tr>
<tr>
<td>0.61Ω</td>
</tr>
</tbody>
</table>

Fig. 11-1
11-1-2 CHECK THE FUEL SYSTEM.

(1) CHECKING THE FUEL IN THE FUEL TANK

Deteriorated fuel or the water mixed in the fuel causes bad starting. If the fuel is deteriorated or the water is mixed, drain the tank and carburetor completely then refuel the fresh gasoline.

**NOTE:** Sometimes when a generator is stored for more than a few months, the gasoline in the tank deteriorates until it lost so much volatility that starting becomes difficult. In that case, replace the fuel with fresh gasoline.

(2) CHECKING THE FUEL FILTER

There are two types of fuel filter attached to the generator. The first type is a disposable filter put in the middle of the fuel line. The second type is a fine mesh filter built in the fuel cock.

- The first type (Disposable type)
  Disconnect the fuel lines and replace the fuel filter with a new one.

- The second type (Filter built in fuel cock)
  a) Remove the fuel tank following the disassembly procedures.
  b) Remove the fuel cock from the tank.
  c) Clean the filter mesh (18).
  d) If the gaskets (15) are broken, replace them with new ones at re-assembly.
(3) CHECKING THE CARBURETOR

- Remove the carburetor from engine.
- Remove the float chamber from the carburetor and check to see if the main jet or the pilot jet has been clogged up. (Refer to Section 10-5-2 on page 59.)
  Use a compressor and high-pressure air to blow the clogged dust or gum out of the jets and fuel passage.
- Remove the float pin and the float.
  Check the needle valve.
  If the needle valve is worn, replace it and the valve seat.
- Clean and re-assemble the carburetor.

11-1-3 CHECK THE COMPRESSION

If the engine's starting difficulty or power drop has not been caused by a faulty ignition or fuel system, the final step is to check the compression of the engine.

1) Check the spark plug.
   Loose or broken spark plug can cause low compression. If the spark plug is broken, replace with a new one.

2) Check the head gasket.
   Remove fuel tank, head cover and cylinder head to check the head cover.
   If the head gasket is broken, replace it with a new one.

3) Remove carbon deposits from the cylinder head and piston top.

4) Check and adjust the tappet clearance.

5) Check the valve system.
   Remove any carbon deposits from the valves, valve seats, intake and exhaust ports and valve guides.
   If the valve face or the valve guide is worn, replace it.
   Check and adjust the tappet clearance when reassembling. (Refer to Sections 10-4-2-(8) and 10-4-2-(9) on pages 51 and 52.)

6) Check the piston and piston rings.
   If the compression is still not sufficient, you'll have to dismantle the engine and examine the piston and piston rings.
   - Disassemble the engine and remove the piston and piston rings.
   - Check the piston rings and grooves.
     Clean off any carbon or gum deposits from the piston rings and grooves.
     If a piston ring is worn, replace with a new one. (Refer to Section 10-4-2-(3) on page 48.)
(28) INSTALLING THE FRONT COVER
Using two M6 x 8 mm flange bolts, install the front cover assembled with the control panel to the base plate. Keep the engine switch set at STOP.

(29) INSTALLING THE FUEL TANK
a) Keep the strainer shaft at the lower part of the fuel tank in a position that will allow the setscrews to be tightened from the opposite direction of the muffler.

b) Insert the flexible shaft extending from the rear side of the engine switch which is mounted on the control panel into the square hole of the strainer shaft.

c) Align the mounting holes at the lateral side of the front cover with those in the bracket which are bolted to the fuel tank. Then, install the fuel tank, using two M6 x 8mm flange bolts.

d) Make sure that the flexible shaft on the control dial side is inserted in the square hole of the strainer shaft, then fasten the flexible shaft.

(30) INSTALLING THE REAR COVER
Align the mounting holes at the lateral side of the rear cover with those in the fuel tank bracket. Then install the rear cover, using two M6 x 8 mm flange bolts. Also align the holes at the lower part of the rear cover with those in the base plate, and install the rear cover by two M6 x 8 mm flange bolts.

NOTE: Pull out the fuel drain pipe of the carburetor through the hole on the rear cover. The frequency changeover switch knob have to be drawn out through the rubber shield.

(31) INSTALLING THE FUEL TANK HANDLE
a) Set the bolt (to secure the tank handle) in the handle and assemble the O-ring to this bolt from the opposite side. Then, tighten the bolt to install the handle to the fuel tank.

NOTE: Be sure to direct the less slanted part of the handle toward the front cover.

b) Insert the rubber tube end over the protrusion of the bolt (for the fuel tank) and push it down to the base of the protrusion.

NOTE: Be sure to keep the air breathe hole at the center of the rubber tube directed upward.

c) Place the handle cover over the handle.

(32) INSTALLING THE FUEL LINE
Insert the fuel line end over the fuel strainer joint (be sure to push the line end down to the joint base), and secure it with the clamp.

(33) INSTALLING THE CHOKE CABLE
a) Insert the choke cable adjusting screw in its hole on the fuel tank bracket.

b) Secure this adjusting screw with the M6 nut and tighten to the midway point of the threaded part.

c) Set the dial of the control panel to STOP, and connect the choke cable end to the lever of the panel.

d) Pull the inner wire of the choke cable to clamp the wire to the choke-lever, using the setscrew.

(34) CONNECTING THE COUPLERS TOGETHER
Connect the coupler (6P) from the generator to the coupler (6P) extending from the control panel. Also connect the stop wire (green) as required.
- Usually the instrument is expensive and difficult to obtain, we suggest instead that you install a new condenser and see if the generator works. If the generator works with a new condenser, the old one is defective.

(6) Check the rotor.
- Disassemble the generator to remove the rotor.
- Unsolder the diode and the resistor from the rotor terminal. Unsolder one wire of each part.

- Check the resistance between the wire ends of rotor winding at the terminals.

<table>
<thead>
<tr>
<th>NORMAL RESISTANCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.5Ω</td>
</tr>
</tbody>
</table>

If the resistance is much different, the rotor is defective.

- Check the insulation resistance across one of the soldered terminals and the rotor core using a megger tester. If the resistance is less than 1 MΩ, the insulation is faulty. Replace the rotor with a new one.
Check the resistance of the resistor.

<table>
<thead>
<tr>
<th>NORMAL RESISTANCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>15Ω</td>
</tr>
</tbody>
</table>

Check the diode.

Touch the positive (RED) probe of the circuit tester to the cathode mark side of the diode, and touch the negative (BLACK) probe to the other side of the diode.

Normal resistance is 16Ω.

Reverse the polarity of the circuit tester. At this time, the resistance is infinity.

[Remedy]

If the diode is defective, replace with a new one.

Fig. 11-8

Fig. 11-9

Fig. 11-10
11-3 NO DC OUTPUT

(1) Check the DC circuit breaker.
- Examine the DC circuit breaker to make sure it is in the “ON” position.
- Sometimes, when a battery with a large capacity is being charged, the charging current exceeds the maximum DC output the generator can produce. This causes the circuit breaker to pop into the “OFF” position. When this is the problem, advise your customer to use a battery charger and take the power from the AC receptacle.

(2) Check the AC output.
- Using a circuit tester, check the AC voltage at the AC receptacle. If no AC voltage is being produced, check the generator following the procedure outlined in Section 11-2.

(3) Check the DC coil.
- Remove the left side cover, right side cover, front panel and the recoil starter.
- Disconnect the green wire and white wire from the rectifier.
- Check the resistance between these wires with a circuit tester.

<table>
<thead>
<tr>
<th>NORMAL RESISTANCE GREEN—WHITE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.7Ω</td>
</tr>
</tbody>
</table>

(4) Check the diode rectifier.
Refering to Section 9-6 on page 29, check the resistance between the terminals of the rectifier with a circuit tester. If the rectifier is defective, replace it with a new one.

11-4 OUTPUT VOLTAGE IS NORMAL AT NO-LOAD, BUT GENERATOR WON’T WORK ON-LOAD.

(1) Check the engine speed.
Start the engine and check the engine speed at no-load. Adjust the engine speed to 3,100 ~ 3,150 r.p.m. for 50 Hz type, and 3,700 ~ 3,750 r.p.m. for 60 Hz type.

(2) Check for over-load.
Check the total wattage of the load(s) applied to the generator. If the generator is over-loaded, remove or turn off some of the appliances.

(3) Check the appliances.
Check the appliances for defects. If any are defective, repair or replace them.
(4) Check the generator insulation.

- (Stop the engine.)

Measure the insulation between the live part (AC receptacle) and the ground terminal.

Any part with an insulation resistance of less than 1 MΩ has faulty insulation that could cause electric shock or leakage.

Replace any such parts.

(5) Check the generator for overheating.

Remove any obstacles that are clogging or blocking the cooling air inlet or the cooling air outlet.
