4-3 LOCATION of SERIAL NUMBER and SPECIFICATION NUMBER

Serial number and specification number are stamped on the LABEL (MODEL NAME) stuck on the end cover.

NOTE: Always specify these numbers when inquiring about the generator or ordering spare parts in order to get correct parts and accurate service.
5. CONSTRUCTION AND FUNCTION

5-1 CONSTRUCTION

5-2 FUNCTION

5-2-1 STATOR
The stator consists of a laminated silicon steel sheet core, a main coil and a condenser coil which are wound in the core slots. The condenser coil excites the rotor field coil which generates AC voltage in the main coil.
5-2-2 CONDENSER

One or two condensers are installed in the control box and are connected to the condenser coil of the stator. These condensers and condenser coil regulate the output voltage.

5-2-3 ROTOR

The rotor consists of a laminated silicon steel sheet core and a field coil which is wound over the core. DC current in the field coil magnetizes the steel sheet core. Two permanent magnets are provided for the primary exciting action.

A diode rectifier and surge absorber is mounted inside of the insulator.
5-2-4 FUSE

(1) The 10 ampere DC fuse mounted on the control panel protects whole DC circuit from getting damage by overload or short circuit.

5-2-5 NO-FUSE BREAKER

The no-fuse breaker protects the generator from getting damage by overloading or short circuit in the appliance. Table 5-1 shows the capacity of no-fuse breaker by each spec. and their object of protection.

Table 5-1
5-2-6 RECEPTACLE and AC PLUG (STD.SPEC.)

These are used for taking AC output power from the generator. A total of five kinds of receptacles, each varying in rated voltage and current from another, are used. Each model has at least one receptacle to deliver the rated generator output. As many AC plugs as the receptacles, each matching the corresponding receptacle, are provided. Table 5-2 shows the rated current for each receptacle. Be careful not to use the receptacles and AC plugs beyond the specified amperage limits to prevent burning.

Note: The generator for U.S.A. market is equipped with NEMA standard receptacles shown in table 5-3. Use the proper plug for connecting appliance to the generator.
5-3 DESCRIPTION of GENERATOR OPERATION

5-3-1 GENERATION of NO-LOAD VOLTAGE

(1) When the generator starts running, the permanent magnet built-in to the rotor generates 3 to 6V of AC voltage in the main coil and condenser coil wound on the stator.

(2) As one or two condensers are connected to the condenser coil, the small voltage at the condenser coil generates a minute current which flows through the condenser coil. At this time, a small flux is produced with which the magnetic force at the rotor’s magnetic pole is intensified. When this magnetic force is intensified, the respective voltages in the main coil and condenser coil rise up. As the current increases, the magnetic flux at the rotor’s magnetic pole increases further. Thus the voltages at the main coil and condenser coil keep rising by repeating this process.

(3) As AC current flows through the condenser coil, the density of magnetic flux in the rotor changes. This change of magnetic flux induces AC voltage in the field coil, and the diode rectifier in the field coil circuit rectifies this AC voltage into DC. Thus a DC current flows through the field coil and magnetizes the rotor core to generate an output voltage in the main coil.

(4) When generator speed reaches 2700 to 2800 rpm (50Hz type) or 3000 to 3300 rpm (60Hz type), the current in the condenser coil and field coil increases rapidly. This acts to stabilize the output voltage of each coils. If generator speed further increases to the rated value, the generator output voltage will reach to the rated value.

5-3-2 VOLTAGE FLUCTUATIONS UNDER LOAD

When the output current flows through the main coil to the appliance, a magnetic flux is produced and serves to increase current in the condenser coil. When current increases, the density of magnetic flux across the rotor core rises. As a result, the current flowing in the field coil increases and the generator output voltage is prevented from decreasing.
5-3-3 FULL POWER SWITCH (Dual Voltage Type)

The full power switch is provided for the dual voltage type to take out the full rated power from one receptacle in each voltage.

Fig. 5-11
Two main coils are wound over stator core. Each main coil outputs half the rated power at the lower voltage (110V or 120V). These main coils are wound to be in the same phase. The full power switch reconnects these main coils in parallel or in series.

Fig. 5-9 shows a circuit diagram. When the full power switch is set for single lower voltage indication (110V or 120V), the switch position is as indicated by the lower solid line in the diagram. Fig. 5-10 is a simplified representation of this circuit, showing the two main coils connected in parallel. In this case, the higher voltage (220V or 240V) at Rec. 3 cannot be taken out. Rec. 2 for the lower voltage can output up to the rated power (up to 30A if the rated current is over 30A), and Rec. 1 can output up to a total of 15A. When the full power switch is set for double voltage indication (110V/220V or 120V/240V), the switch position is as indicated by the upper dotted line in Fig. 5-9. Fig. 5-11 is a simplified representation of this circuit, showing the two main coils connected in series. In this case, power can be taken simultaneously from the receptacles for both voltages. Rec. 3 for the higher voltage can output up to the rated power, but Rec. 1 and Rec. 2 for the lower voltage can output only up to half the rated power each.

Table 5-4 is a summary of the above explanation. Select the proper output voltage by full power switch in accordance with the appliance to be used.

5-3-4 VOLTAGE CHANGEOVER SWITCH

The generator of 50Hz 110V/220V dual voltage type for U.K. is provided with voltage changeover switch instead of full power switch. The output voltage is selected from 110V and 220V by turning this switch and both voltages cannot be taken out simultaneously.
6. SAFETY PRECAUTIONS

1. Use extreme caution near fuel. A constant danger of explosion or fire exists.
   Do not fill the fuel tank while the engine is running. Do not smoke or use open flame near the fuel tank. Be careful not to spill fuel when refueling. If spilt, wipe it and let dry before starting the engine.

2. Do not place inflammable materials near the generator.
   Be careful not to put fuel, matches, gunpowder, oily cloth, straw, and any other inflammables near the generator.

3. Do not operate the generator in a room, cave or tunnel. Always operate in a well-ventilated area.
   Otherwise the engine may overheat and also, the poisonous carbon monoxide contained in the exhaust gases will endanger human lives. Keep the generator at least 1 m (4 feet) away from structures or facilities during use.

4. Operate the generator on a level surface.
   If the generator is tilted or moved during use, there is a danger of fuel spillage and a chance that the generator may tip over.

5. Do not operate with wet hands or in the rain.
   Severe electric shock may occur. If the generator is wet by rain or snow, wipe it and thoroughly dry it before starting.
   Don’t pour water over the generator directly nor wash it with water.
   If the generator is wet with water, the insulations will be adversely affected and may cause current leakage and electric shock.

6. Do not connect the generator to the commercial power lines.
   This may cause a short-circuit or damage to the generator. Use a transfer switch for connecting with indoor wiring.

   NOTE: The parts numbers of the transfer switches and of the plastic box to store them are as shown in Table 6-1.

7. Use a fuse of the correct capacity. (DC output)
   If the generator rpm is increased excessively in the overload condition by using an over rated fuse, the generator may be burnt.

   CAUTION: If the fuse is burnt or the circuit breaker tripped off as a result of using an electrical appliance, the cause can be an overload or a short-circuit. In such a case, stop operation immediately and carefully check the electrical appliance and AC plugs for faulty wiring.
7. RANGE OF APPLICATIONS

Generally, the power rating of an electrical appliance indicates the amount of work that can be done by it. The electric power required for operating an electrical appliance is not always equal to the output wattage of the appliance. The electrical appliances generally have a label showing their rated voltage, frequency, and power consumption (input wattage). The power consumption of an electrical appliance is the power necessary for using it. When using a generator for operating an electrical appliance, the power factor and starting wattage must be taken into consideration.

In order to determine the right size generator, it is necessary to add the total wattage of all appliances to be connected to the unit.

Refer to the followings to calculate the power consumption of each appliance or equipment by its type.

(1) Incandescent lamp, heater, etc. with a power factor of 1.0

Total power consumption must be equal to or less than the rated output of the generator.

Example: A rated 3000W generator can turn thirty 100W incandescent lamps on.

(2) Fluorescent lamps, mercury lamps, etc. with a smaller power factor

Select a generator with a rated output equivalent to 1.2 to 2 times of the power consumption of the load.

Example: A 400W mercury lamp requires 600W to 700W power source to be turned on.

A rated 3000W generator can drive one or two 400W mercury lamps without power factor correction capacitors.

NOTE1: If a power factor correction capacitor is not applied to the mercury lamp or fluorescent lamp, the more power shall be required to drive those lamps.

A rated 3000W generator can drive one or two 400W mercury lamps without power factor correction capacitors.

NOTE2: Nominal wattage of the fluorescent lamp generally indicates the output wattage of the lamp.

Therefore, if the fluorescent lamp has no special indication as to the power consumption, efficiency should be taken into account as explained in Item (5) on the following page.

(3) Motor driven tools and light electrical appliances

Generally the starting wattage of motor driven tools and light electrical appliances are 1.2 to 3 times larger than their running wattage.

Example: A rated 250W electric drill requires a 400W generator to start it.

(4) Initially loaded motor driven appliances such as water pumps, compressors, etc.

These appliances require large starting wattage which is 3 to 5 times of running wattage.

Example: A rated 900W compressor requires a 4500W generator to drive it.

NOTE1: Motor-driven appliances require the aforementioned generator output only at the starting. Once their motors are started, the appliances consume about 1.2 to 2 times their rated power consumption so that the excess power generated by the generator can be used for other electrical appliances.

NOTE2: Motor-driven appliances mentioned in Items (3) and (4) vary in their required motor starting power depending on the kind of motor and start-up load. If it is difficult to determine the optimum generator capacity, select a generator with a larger capacity.
(5) Appliances without any indication as to power consumption

Some appliances have no indication as to power consumption; but instead the work load (output) is indicated. In such a case, power consumption is to be worked out according to the numerical formula mentioned below.

\[
\frac{\text{Output of electrical appliance}}{\text{Efficiency}} = \text{Power consumption}
\]

Efficiencies of some electrical appliances are as follows:

- Single-phase motor: 0.6 ~ 0.75  The smaller the motor, the lower the efficiency.
- Three-phase motor: 0.65 ~ 0.9
- Fluorescent lamp: 0.7 ~ 0.8

**Example 1:** A 40W fluorescent lamp means that its luminous output is 40W. Its efficiency is 0.7 and accordingly, power consumption will be \(40 \div 0.7 = 57W\). As explained in **Item(2)**, multiply this power consumption value of 57W by 1.2 - 2 and you will get the figure of the necessary capacity of a generator. In other words, a generator with a rated output of 1000W capacity can light nine to fourteen 40W fluorescent lamps.

**Example 2:** Generally speaking, a 400W motor means that its work load is 400W. Efficiency of this motor is 0.7 and power consumption will be \(400 \div 0.7 = 570W\). When this motor is used for a motor-driven tool, the capacity of the generator should be multiplied by 1.2 to 2 and 570W as explained in the **Item(3)**.

NOTES: Wiring between generator and electrical appliances

1. Allowable current of cable
   Use a cable with an allowable current that is higher than the rated input current of the load (electrical appliance). If the input current is higher than the allowable current of the cable used, the cable will become excessively heated and deteriorate the insulation, possibly burning it out. Table 7-2 shows cables and their allowable currents for your reference.

2. Cable length
   If a long cable is used, a voltage drop occurs due to the increased resistance in the conductors decreasing the input voltage to the load (electrical product). As a result, the load can be damaged. Table 7-2 shows voltage drops per 100 meters of cable.

Table 8-1

The "Dr. Robin" generator tester can be ordered from Robin generator distributors by the following part number.

Dr. Robin Part Number : 388-47565-08

If you do not have a "Dr. Robin" generator tester, use the instruments described in the following section for checking generator parts.
8-1-2 INSTRUMENTS

(1) VOLTMETER
AC voltmeter is necessary. The approximate AC voltage ranges of the voltmeters to be used for various types of generators are as follows:
- 0 to 150V: Type with an output voltage of 110 or 120V
- 0 to 300V: Type with an output voltage of 220, 230 or 240V
- 0 to 150V, 0 to 330V: Dual voltage type

(2) AMMETERS
AC ammeter is necessary. An AC ammeter with a range that can be changed according to the current rating of a given generator is most desirable. (About 10A, 20A, 100A)

(3) FREQUENCY METER
Frequency range: About 45 to 65Hz
NOTE: Be careful of the frequency meter's input voltage range.
(4) CIRCUIT TESTER
Used for measuring resistance, etc.

(5) MEGGER TESTER
Used for measuring generator insulation resistance.
Select one with testing voltage range of 500V.

(6) TACHOMETER
There are various types of tachometers, such as contactless type, contact type, and strobe type. The contact type can be used only when the generator and engine have been disassembled. The contactless type is recommended.
8-2 AC OUTPUT MEASURING

Use a circuit like the shown in Fig.8-8 for measuring AC output. A hot plate or lamp with a power factor of 1.0 may be used as a load. Adjust the load and rpm. and check that the voltage range is as specified in Table 8-2 at the rated amperage and rated rpm.

Table 8-2

8-3 MEASURING INSULATION RESISTANCE

Use a "Dr. Robin" generator tester in megger tester mode or use a megger tester to check the insulation resistance. Connect a megger tester to one of receptacle output terminals and the ground terminal, then measure the insulation resistance. An insulation resistance of 1 megohm or more is normal. (The original insulation resistance at the time of shipment from the factory is 10 megohm or more.) If it is less than 1 megohm, disassemble the generator and measure the insulation resistance of the stator, rotor and control panel individually.

- **STATOR**
  1. Measure the insulation resistance between BLUE lead and the core.
  2. Measure the insulation resistance between WHITE lead and the core.
  3. Measure the insulation resistance between YELLOW lead and the core.
  4. Measure the insulation resistance between BROWN lead and the core.
• **ROTOR**
  Measure the insulation across one of the soldered terminals of the rotor and the core.

![Fig. 8-11](image)

• **CONTROL PANEL**
  Measure the insulation resistances between the live parts and the grounded parts.

![Fig. 8-12](image)

Any part where the insulation resistance is less than $1\,\text{M}\Omega$ has faulty insulation, and may cause electric leakage and electric shock. Replace the faulty part.
9. CHECKING FUNCTIONAL MEMBERS

9-1 PILOT LAMP and VOLTMETER
Check the pilot lamp and the voltmeter if it is turned on by applying specific voltage. Pilot lamp and voltmeter cannot be checked with circuit tester because its resistance is too large. (See Fig.9-1.)

Pilot lamp should be turned on at 70 to 120V.

9-2 AC RECEPTACLES
Using a "Dr. Robin" or a circuit tester, check continuity between the two terminals at the rear of the AC receptacles while the receptacle is mounted on the control panel. When continuity is found between the output terminals of the receptacle with a wire connected across these terminals, the AC receptacle is normal. When the wire is removed and no continuity is found between these terminals, the receptacles are also normal.
9-3 CIRCUIT BREAKER

Check continuity between each of two terminals at the rear of the circuit breaker while it is mounted on the control panel. Normally, there is continuity between each of the two when the circuit breaker is on while there is no continuity when the circuit breaker is off.

9-4 STATOR

Disengage connectors on the wires from stator and check the resistance between wires with a “Dr. Robin” or a circuit tester referring to the following table.

Erroneous reading will also occur when there is a wide variation of resistance among coil windings or when measurement is performed at ambient temperatures different from 20°C (68°F).

9-6 CONDENSER

- Use a “Dr. Robin” in capacitance meter mode to check the capacity of condensers. (See Fig.9-6).

NOTE: Be sure to discharge condensers by shorting condenser leads each other before checking their capacitance, or the accurate reading cannot be obtained.

NOTE 2: "Continuity" means forward direction characteristics of the diode, and different from short circuit condition (in which a pointer of the tester goes out of its normal scale), shows resistance to some extent. When results of the checking indicates failure even in one section, replace with a new one.

NOTE 3: Simpson brand analogue testers are digital.

10. DISASSEMBLY AND ASSEMBLY

10-1 PREPARATION and PRECAUTIONS

1) Be sure to memorize the location of individual parts when disassembling the generator so that the generator can be reassembled correctly. Tag the disassembled part with the necessary information to facilitate easier and smoother reassembly.
2) For more convenience, divide the parts into several groups and store them in boxes.
3) To prevent bolts and nuts from being misplaced or installed incorrectly, place them temporarily back at their original position.
4) Handle disassembled parts with care; clean them before reassembly using a neutral cleaning fluid.
5) Use all disassembly/assembly tools properly, and use the proper tool for each specific job.

If such an instrument is unavailable, the condenser can be checked by replacing with a new one. If the generator performs good with new condenser, the cause of trouble is defect in original condenser.

11-1-2 CHECKING STATOR

- Remove control panel and disconnect stator wires at the connectors.
- Measure the resistance between terminals on stator leads. (See Fig. 11-2)
  Refer to Table 9-1 for normal resistance.
  If stator is faulty, replace it with a new one.

Fig. 11-2
Check the insulation resistance between stator core and each stator lead using a Dr. Robin generator tester in megger tester mode or a megger tester. (Fig. 11-3) If insulation is bad, replace stator with a new one.

**11-1-3 CHECKING ROTOR**

(1) CHECKING FIELD COIL

- Remove rear cover and stator.

Using a Dr. Robin or a circuit tester, measure the resistance of the field coil at the terminals.

**NOTE 1:** Because a diode is soldered to the coil ends at the terminals, resistance may be measured only when tester probes touch the terminals in one combination of polarity. Therefore, if no resistance reading appears, try checking in reverse polarity.

[Remedy]

If the resistance is not normal, replace rotor with a new one.
Measure the insulation across one of the soldered terminals of the rotor and the core. (Fig.11-6)

If insulation is bad, replace rotor with a new one.

11-2 AC VOLTAGE IS TOO HIGH OR TOO LOW

11-2-1 CHECKING ENGINE SPEED
If the engine speed is too high or too low, adjust it to the rated r.p.m.

[How to adjust engine r.p.m.]
- Loosen the lock nut on the adjusting screw.
- Turn the adjusting screw clockwise to decrease engine speed or counter-clockwise to increase engine speed.

Normal engine speed at no load is:
- 3100 - 3150 r.p.m. for 50Hz type
- 3700 - 3750 r.p.m. for 60Hz type

11-2-2 CHECKING CONDENSER
Check condenser referring to Step 11-1-1.

11-2-3 CHECKING STATOR
Check stator referring to Step 11-1-2.

11-2-4 CHECKING ROTOR
Check rotor referring to Step 11-1-3.
11-3 AC VOLTAGE IS NORMAL AT NO-LOAD, BUT THE LOAD CANNOT BE APPLIED.

11-3-1 CHECK THE ENGINE SPEED.
If the engine speed is low, adjust it to the rated r.p.m.
* Refer to Step 11-2-1 for engine speed adjustment.

11-3-2 CHECK THE TOTAL WATTAGE OF APPLIANCES CONNECTED TO THE GENERATOR.
Refer to Section 7 “RANGE OF APPLICATIONS” for the wattage of the appliances.
If the generator is over-loaded, reduce the load to the rated output of the generator.

11-3-3 CHECK THE APPLIANCE FOR TROUBLE.
If the appliance is faulty, repair it.

11-3-4 CHECK IF THE ENGINE IS OVERHEATED.
If the cooling air inlet and/or cooling air outlet is clogged with dirt, grass, chaff or other debris, remove it.

11-3-5 CHECK THE INSULATION OF THE GENERATOR.
Stop the engine. Measure the insulation resistance between the live terminal of the receptacle and the ground terminal.
If the insulation resistance is less than 1 MΩ, disassemble the generator and check the insulation resistance of the stator, rotor and the live parts in the control box. (Refer to Section 8-3.)
Any part where the insulation resistance is less than 1 MΩ, the insulation is faulty and may cause electric leakage.
Replace the faulty part.
11-4 NO DC OUTPUT

11-4-1 CHECK THE AC OUTPUT.
Check the generator by following Step 11-1-1 through Step 11-1-3.

11-4-2 CHECK THE DC FUSE.
Check the fuse in the fuse holder.
If the fuse is blown, check for the cause of fuse blowing, and then replace with a new one.
FUSE : 10A

NOTE: If the DC output is used to charge a large capacity battery or an over-discharged battery, an excessive current may flow causing fuse blow.

11-4-3 CHECK THE WIRING.
Check all the wires to be connected correctly.

11-4-4 CHECK THE DIODE RECTIFIER.
Remove the control panel and check the diode rectifier with a circuit tester.
Refer to Section 9-7 “DIODE RECTIFIER” for the checking procedure.

11-4-5 CHECK THE DC COIL
Check the resistance between two brown leads from stator with a circuit tester.

If the resistance reading is much larger or smaller than the specified value, the DC coil of the stator is faulty. Replace stator with a new one.
11-5 IDLE CONTROL (OPTIONAL EQUIPMENT)

11-5-1 ENGINE SPEED IS NOT INCREASED WHEN A LOAD IS APPLIED

1) Inspect the solenoid bracket.
   Check the bend angle of solenoid bracket.
   If the bracket is distorted, correct the angle
   with proper tool.

(2) Check the wattage of load applied to the generator.
   If the generator is loaded over the rated wattage, the engine speed can not be increased.
   Most induction loads such as electric motor or electric tools or welding machine require three to five
   times large wattage of their ratings at starting.
   This starting wattage must not exceed the rated output of the generator.

(3) Check the slow set r.p.m.
   The normal idling speed by the IDLE CONTROL is as follows:
   
   RGX2400, 3500 .......... 3150 ~ 3200 r.p.m.
   RGX5500 ................ 2700 ~ 2800 r.p.m.
   Adjust the idling speed monitoring the voltmeter so that it indicates between 75 volt and
   85 volt.
   • Turn the adjusting screw to adjust the slow speed.
(4) Check the wiring through ZCT on the IDLE CONTROL UNIT BOARD.

A) Single Voltage Type
Make sure that an output wire from main coil is passing through the ZCT on the IDLE CONTROL UNIT.

B) Dual Voltage Type
Check that two output wires (black wire and red wire) from main coils are passing through the ZCT on the IDLE CONTROL UNIT in the same direction.

(5) Checking the IDLE CONTROL UNIT
Check the resistance between six leads of IDLE CONTROL UNIT with circuit tester.

11-5-2 ENGINE SPEED IS NOT REDUCED WHEN LOAD IS OFF.

(1) Check the distortion of the SOLENOID BRACKET as shown in step 11-5-1-(1).

(2) Check the FUSE on wiring of IDLE CONTROL UNIT.
   - Remove the control panel from control box.
   - Check the FUSE in the fuse holder of IDLE CONTROL UNIT.
     If fuse is blown, replace with a new one. (FUSE : 0.3A)

(3) Check the wiring of SOLENOID.
    Check two leads from SOLENOID are securely connected.

(4) Check the wiring of IDLE CONTROL UNIT.
