DC output .................. 100W

The voltage curve shown in the left indicates the characteristic of DC output when charging a battery. The voltage may be decreased by 20% when the resistance load is applied.

NOTE: It is possible to use both DC and AC outputs simultaneously up to the rated output in total.
3. FEATURES

3-1 BRUSHLESS ALTERNATOR
Newly developed brushless alternator eliminates troublesome brush maintenance.

3-2 CONDENSER TYPE VOLTAGE REGULATOR
A trouble free condenser type voltage regulator ensures a stable voltage under all working conditions.

3-3 OIL SENSOR
Oil sensor automatically shuts off the engine whenever the oil level falls down below the lower limit to protect the engine from seizure.

3-4 QUIET OPERATION
Robin RGX series generator delivers a quiet operation with:
- A large super silent muffler.
- A quiet 4-stroke Robin engine.
- A silent cyclone air cleaner.

3-5 NO RADIO NOISE
Noise suppressor spark plug and spark plug cap are equipped standard to prevent radio frequency interference.

3-6 LARGE FUEL TANK
The large fuel tank allows more than 5 to 10 hours of continuous operation which is sufficient for a half day or one day work without refueling.

3-7 RUGGED TUBULAR FRAME
Full cradle type rugged tubuler frame protects the generator all around.

3-8 COMPACT AND LIGHT WEIGHT
Newly developed brushless alternator enabled the RGX generators to be very compact in size and light in weight.

3-9 MINIMAL MAINTENANCE
- A brushless alternator release the operator from periodical brush maintenance.
- A trouble free condenser type voltage regulator.
- A drip-proof alternator design.
- No-fuse circuit breakers.
- An electronic pointless ignition system.
- A dust-proof cyclone air cleaner.

3-10 LONG-LIFE DURABILITY
The heavy-duty 4 stroke Robin engine and virtually maintenance-free brushless alternator ensure greater durability with:
- A brushless alternator with a condenser voltage regulator.
- Full rubber mount in a sturdy tubular frame.
- A forged steel crankshaft supported by two main ball bearings.
- A pointless electronic ignition system.
- A cast iron cylinder liner.
- A forged aluminum connecting rod.

4-3 LOCATION of SERIAL NUMBER and SPECIFICATION NUMBER

Serial number and specification number are stamped on the LABEL (MODEL NAME) stuck on the side wall of control box.

NOTE: Always specify these numbers when inquiring about the generator or ordering spare parts in order to get correct parts and accurate service.
5. CONSTRUCTION AND FUNCTION

5-1 CONSTRUCTION

REAR COVER  ROTOR COMPLETE  STATOR COMPLETE

MOUNT RIBBER  STATOR BOLT  BALL BEARING  THROUGH BOLT  FRONT COVER

5-2 FUNCTION

5-2-1 STATOR

The stator consists of a laminated silicon steel sheet core, a main coil and a condenser coil which are wound in the core slots.

The condenser coil excites the rotor field coil which generates AC voltage in the main coil.
5-2-2 CONDENSER

One or two condensers are installed in the control box and are connected to the condenser coil of the stator. These condensers and condenser coil regulate the output voltage.

5-2-3 ROTOR

The rotor consists of a laminated silicon steel sheet core and a field coil which is wound over the core. DC current in the field coil magnetizes the steel sheet core. Two permanent magnets are provided for the primary exciting action.

A diode rectifier and surge absorber is mounted inside of the insulator.
5-2-4 DC FUSE (OPTION)

The 10 ampere DC fuse mounted on the control panel protects whole DC circuit from getting damage by overload or short circuit.

5-2-5 NO-FUSE BREAKER

The No-Fuse breaker protects the generator from getting damage by overloading or short circuit in the appliance. Table 5-1 shows the capacity of No-Fuse breaker by each spec. and their object of protection.

5-2-6 RECEPTACLE and AC PLUG (STD. SPEC.)

These are used for taking AC output power from the generator. A total of six kinds of receptacles, each varying in rated voltage and current from another, are used. Each model has at least one receptacle to deliver the rated generator output. As many AC plugs as the receptacles, each matching the corresponding receptacle, are provided. Table 5-2 shows the rated current for each receptacle. Be careful not to use the receptacles and AC plugs beyond the specified amperage limits to prevent burning.

5-3 GENERATOR OPERATION

5-3-1 GENERATION of NO-LOAD VOLTAGE

1. When the generator starts running, the permanent magnet built-in to the rotor generates 3 to 6V of AC voltage in the main coil and condenser coil wound on the stator.

2. As one or two condensers are connected to the condenser coil, the small voltage at the condenser coil generates a minute current which flows through the condenser coil. At this time, a small flux is produced with which the magnetic force at the rotor's magnetic pole is intensified. When this magnetic force is intensified, the respective voltages in the main coil and condenser coil rise up. As the current increases, the magnetic flux at the rotor's magnetic pole increases further. Thus the voltages at the main coil and condenser coil keep rising by repeating this process.

3. As AC current flows through the condenser coil, the density of magnetic flux in the rotor changes. This change of magnetic flux induces AC voltage in the field coil, and the diode rectifier in the field coil circuit rectifies this AC voltage into DC. Thus a DC current flows through the field coil and magnetizes the rotor core to generate an output voltage in the main coil.

4. When generator speed reaches 2700 to 2800 rpm (50Hz type) or 3000 to 3300 rpm (60Hz type), the current in the condenser coil and field coil increases rapidly. This acts to stabilize the output voltage of each coils. If generator speed further increases to the rated value, the generator output voltage will reach to the rated value.

5-3-2 VOLTAGE FLUCTUATIONS UNDER LOAD

When the output current flows through the main coil to the appliance, a magnetic flux is produced and serves to increase current in the condenser coil. When current increases, the density of magnetic flux across the rotor core rises. As a result, the current flowing in the field coil increases and the generator output voltage is prevented from decreasing.
5-3-3 FULL POWER SWITCH

The full power switch is provided for the dual voltage type to take out the full rated power from one receptacle in each voltage.

*Table 5-4*
Two main coils are wound over stator core. Each main coil outputs half the rated power at the lower voltage (110V or 120V). These main coils are wound to be in the same phase. The full power switch reconnects these main coils in parallel or in series.

Fig. 5-9 shows a circuit diagram. When the full power switch is set for single lower voltage indication (110V or 120V), the switch position is as indicated by the lower solid line in the diagram. Fig. 5-10 is a simplified representation of this circuit, showing the two main coils connected in parallel. In this case, the higher voltage (220V or 240V) at Rec. 3 cannot be taken out. Rec. 2 for the lower voltage can output up to the rated power (up to 30A if the rated current is over 30A), and Rec. 1 can output up to a total of 15A.

When the full power switch is set for double voltage indication (110V/220V or 120V/240V), the switch position is as indicated by the upper dotted line in Fig. 5-9. Fig. 5-11 is a simplified representation of this circuit, showing the two main coils connected in series. In this case, power can be taken simultaneously from the receptacles for the both voltages. Rec. 3 for the higher voltage can output up to the rated power, but Rec. 1 and Rec. 2 for the lower voltage can output only up to half the rated power each.

Table 5-4 is a summary of the above explanation. Select the proper output voltage by full power switch in accordance with the appliance to be used.
5-4 ELECTRONIC IGNITION SYSTEM

The electronic ignition system features a power transistor as the current control element. Therefore, the ignition system is an electronic contact point-free type that operates with the power transistor impulses controlling the current. This system is also called TIC (transistor igniter circuit) and is virtually free of ignition failure which generally results from contamination of the contact points, a typical problem with contact type ignition systems.

Because this ignition system has no contact points, it is not affected by moisture, oil, dust, or other contaminants. As a result, this electronic ignition system ensures sure and positive ignition with reduced maintenance.

The TIC mechanism consists of a transistor-incorporated ignition coil and a permanent magneto built-in flywheel which is press-fitted on the rotor shaft of the generator.

![Diagram of an electronic ignition system](image)

**Fig. 5-13**

(1) When the permanent magneto built-in flywheel starts rotating, power is generated in the primary coil of the ignition coil and current flows to the resistor $\text{②}$.

   From the resistor, current flows to the power transistor. With this current, the power transistor turns on, releasing current $\text{⑤}$. This stage corresponds to the closing of contact points.

(2) As the flywheel comes to the point of ignition, the ignition timing detecting circuit is activated while the current $\text{③}$ is flowing through the circuit.

When the ignition timing detecting circuit is activated, the signal transmitter transistor actuates with current $\text{④}$ flowing. When current $\text{④}$ starts flowing, current $\text{⑥}$ flowing through the power transistor is cut quickly. As a result, high voltage is produced in the secondary coil and this voltage is applied simultaneously to the spark plug which ignites for ignition. This stage corresponds to the opening of contact points.
5-5 OIL SENSOR

5-5-1 DESCRIPTION

- The oil sensor mainly functions to detect position of the surface of engine oil in the crankcase of engines for general use and to stop the engine automatically when the oil level goes down below the lower limit specified. This prevents seizure of engine from occurring due to insufficient amount of oil in the crankcase.

- Since the sensor has been designed to consume a part of power supplied to the igniter to energize its electronics circuit, any other external power supply is not necessary so that it can be mounted at the oil filler port.

Introduction of newly developed sensing principle features super durability and no change with the passage of time as it does not use any moving part.

Merits due to introduction of electrical conductivity detection are as follows;

1. It has resistance to mechanical shocks and property of no change with the passage of time as sensing element consists simply of electrodes having no moving parts.
2. At the same time, it is capable of detecting the oil level stably as it is not influenced by engine vibrations.
3. No error occurs due to foam and flow of the oil.
4. Influence against the ignition system or the electronics units can be neglected because an electric current supplied to the sensor can be decreased.

5-5-2 PRINCIPLE OF SENSING OIL LEVEL

There is a great difference between electric resistance of air and that of oil. Since the resistance of air is far higher than that of oil, more electric current passes through the oil than through the air, although absolute value of the current is very small.

The sensor detects this current difference and make use of it.

The sensor judges the oil quantity, by comparing a current flowing across a pair of electrodes (inner and outer) with the reference, in such a way that if a current flows between the electrodes more than the reference, sufficient oil is in the crankcase, on the other hand, if a current flows less than the reference, oil is not sufficient.

Since an electric current is flown to detect oil quantity, this is called the “electrical conductivity detection” type of sensor.

The oil level to be detected is determined by the length of electrodes and their mounting positions with the engine.

5-5-3 HOW IT OPERATES

[Power supply]
The sensor makes use of a part of primary power source for ignition of the engine (igniter) to drive the sensor circuit. Power to the sensor can usually be derived from the “stop button” by branching wires out.
[Judgement of oil level]
When sufficient oil is in the crankcase, both of inner and outer electrodes are immersed in the oil through which current flows across the electrodes. The sensor judges that oil in the crankcase is sufficient.
When oil level goes down and the inner electrode is exposed to the air due to consumption of oil, no current flow between the electrodes as air is considered to be electrically non-conductive.
The sensor in this case judges that oil is insufficient.

[Decision of oil shortage]
Oil level at the electrodes may go down momentarily probably due to the engine being slanted or affected by vibration even if a sufficient oil is in the crankcase.
For that reason, the sensor has an electronic timer circuit to prevent it from interpreting as short of oil when amount of oil is sufficient. The sensor has been designed so that the engine is to be stopped only when oil-shortage is detected for 5 seconds uninterrupted.
The timer employs an integration circuit and it is to be reset when the inner electrode is soaked in the oil again before the sensor decides it as oil-shortage.
The oil level where the sensor decides as oil-shortage, when oil level goes down gradually, is called “threshold level”.

[Automatic stop of engine]
When the sensor decides as oil-shortage, it makes the engine to stop running automatically for protection of engine.
Once the stopping circuit is activated, it keeps functioning until it confirms that the engine has made a complete stop, then the circuit stops functioning automatically.

5-5-4 BLOCK DIAGRAM OF THE CIRCUIT

![Block Diagram of the Circuit](image)

Fig. 5-15

1. Power circuit ………….. This rectifies a part of power to the igniter and regulates it to supply the stabilized power to necessary circuits.
2 Detection circuit……..This detects quantity of oil, sufficient or not, according to difference of electric resistance across inner and outer electrodes.

3 Delay circuit ………..This his prevents the sensor from making an unnecessary stop of the engine by momentary lowering of the oil level due to the engine being slanted or affected by vibration in spite of sufficient oil in the crankcase.

4 Stopping circuit……….This automatically stops the engine running. Also, the LED indicator for warning can be lit while the engine is being stopped. We have the wires to be connected to LED available.

5-5-5 CAUTIONS TO BE TAKEN ON HANDLING THE SENSOR

(1) Oil sensor unit
   ① Be sure not to damage each wire. Broken or short-circuited power supply wires and/or a grounding wire in particular may lead to malfunction or breakdown.

   ② The sensor is not interchangeable from engine to engine because the sensor is to be exclusively installed individually in each engine employed.

(2) Mounting and wiring of oil sensor unit
   ① Although this has been designed to have enough anti-noise properties in practical use, do not route the sensor wirings in the vicinity of noise-generating sources such as ignition plugs or high voltage cords. This may cause malfunction or breakdown.

   ② Since capacity of power source is limited, current flown in the electronic circuit of the sensor is kept as low as possible. Be sure to use terminals with a high contact reliability of more than that of tinned terminals.

(3) Operation of oil sensor
   ① If operating with the engine kept tilted, oil surface inside of the engine varies and the correct oil level can not to be detected which in turn obstructs the preventing function of engine seizure. Operate the engine by keeping it level.

   ② When starting the engine with an insufficient oil in the crankcase, engine starts once then it stops automatically after it runs for 5 seconds.

   ③ When the engine has been stopped by the oil sensor, voltage remained in the electronic circuit prevents the sensor from being re-started for 3 seconds after the engine stop. Try to re-start the engine after 3 seconds or more.
6. SAFETY PRECAUTIONS

1. Use extreme caution near fuel. A constant danger of explosion or fire exists.
   Do not fill the fuel tank while the engine is running. Do not smoke or use open flame near the fuel tank. Be careful not to spill fuel when refueling. If spilt, wipe it and let dry before starting the engine.

2. Do not place inflammable materials near the generator.
   Be careful not to put fuel, matches, gunpowder, oily cloth, straw, and any other inflammables near the generator.

3. Do not operate the generator in a room, cave or tunnel. Always operate in a well-ventilated area.
   Otherwise the engine may overheat and also, the poisonous carbon monoxide contained in the exhaust gases will endanger human lives. Keep the generator at least 1 m (4 feet) away from structures or facilities during use.

4. Operate the generator on a level surface.
   If the generator is tilted or moved during use, there is a danger of fuel spillage and a chance that the generator may tip over.

5. Do not operate with wet hands or in the rain.
   Severe electric shock may occur. If the generator is wet by rain or snow, wipe it and thoroughly dry it before starting.
   Don’t pour water over the generator directly nor wash it with water.
   If the generator is wet with water, the insulations will be adversely affected and may cause current leakage and electric shock.

6. Do not connect the generator to the commercial power lines.
   This may cause a short-circuit or damage to the generator.
   Use a transfer switch (Optional parts) for connecting with indoor wiring.

   NOTE: The parts numbers of the transfer switches and of the plastic box to store them are as shown in Table 6-1.

7. Use a fuse of the correct capacity. (DC output)
   If the generator rpm is increased excessively in the overload condition by using an over rated fuse, the generator may be burnt.

   CAUTION: If the fuse is burnt or the circuit breaker tripped off as a result of using an electrical appliance, the cause can be an overload or a short-circuit.
   In such a case, stop operation immediately and carefully check the electrical appliance and AC plugs for faulty wiring.
7. RANGE OF APPLICATIONS

Generally, the power rating of an electrical appliance indicates the amount of work that can be done by it. The electric power required for operating an electrical appliance is not always equal to the output wattage of the appliance. The electrical appliances generally have a label showing their rated voltage, frequency, and power consumption (input wattage). The power consumption of an electrical appliance is the power necessary for using it. When using a generator for operating an electrical appliance, the power factor and starting wattage must be taken into consideration.

In order to determine the right size generator, it is necessary to add the total wattage of all appliances to be connected to the unit. Refer to the followings to calculate the power consumption of each appliance or equipment by its type.

(1) **Incandescent lamp, heater, etc. with a power factor of 1.0**

Total power consumption must be equal to or less than the rated output of the generator.

**Example:** A rated 3000W generator can turn thirty 100W incandescent lamps on.

(2) **Fluorescent lamps, motor driven tools, light electrical appliances, etc. with a smaller power factor**

Select a generator with a rated output equivalent to 1.2 to 2 times of the power consumption of the load.

Generally the starting wattage of motor driven tools and light electrical appliances are 1.2 to 3 times larger than their running wattage.

**Example:** A rated 250W electric drill requires a 400W generator to start it.

**NOTE1:** If a power factor correction capacitor is not applied to the fluorescent lamp, the more power shall be required to drive the lamps.

**NOTE2:** Nominal wattage of the fluorescent lamp generally indicates the output wattage of the lamp. Therefore, if the fluorescent lamp has no special indication as to the power consumption, efficiency should be taken into account as explained in Item (5) on the following page.

(3) **Mercury lamps with a smaller power factor**

Loads for mercury lamps require 2 to 3 times the indicated wattage during start-up.

**Example:** A 400W mercury lamp requires 800W to 1200W power source to be turned on. A rated 3000W generator can power two or three 400W mercury lamps.

(4) **Initially loaded motor driven appliances such as water pumps, compressors, etc.**

These appliances require large starting wattage which is 3 to 5 times of running wattage.

**Example:** A rated 900W compressor requires a 4500W generator to drive it.

**NOTE1:** Motor-driven appliances require the aforementioned generator output only at the starting. Once their motors are started, the appliances consume about 1.2 to 2 times their rated power consumption so that the excess power generated by the generator can be used for other electrical appliances.

**NOTE2:** Motor-driven appliances mentioned in Items (3) and (4) vary in their required motor starting power depending on the kind of motor and start-up load. If it is difficult to determine the optimum generator capacity, select a generator with a larger capacity.
(5) Appliances without any indication as to power consumption

Some appliances have no indication as to power consumption; but instead the work load (output) is indicated. In such a case, power consumption is to be worked out according to the numerical formula mentioned below.

\[
\frac{\text{Output of electrical appliance}}{\text{Efficiency}} = \text{Power consumption}
\]

Efficiencies of some electrical appliances are as follows:

- Single-phase motor .................. 0.6 to 0.75 (The smaller the motor, the lower the efficiency.)
- Fluorescent lamp ..................... 0.7 to 0.8

**Example 1:** A 40W fluorescent lamp means that its luminous output is 40W. Its efficiency is 0.7 and accordingly, power consumption will be \(40 \div 0.7 = 57\)W. As explained in Item(2), multiply this power consumption value of 57W by 1.2 to 2 and you will get the figure of the necessary capacity of a generator. In other words, a generator with a rated output of 1000W capacity can light nine to fourteen 40W fluorescent lamps.

**Example 2:** Generally speaking, a 400W motor means that its work load is 400W. Efficiency of this motor is 0.7 and power consumption will be \(400 \div 0.7 = 570\)W. When this motor is used for a motor-driven tool, the capacity of the generator should be multiplied by 1.2 to 3 and 570W as explained in the Item(3).

NOTES: Wiring between generator and electrical appliances

1. Allowable current of cable
   Use a cable with an allowable current that is higher than the rated input current of the load (electrical appliance). If the input current is higher than the allowable current of the cable used, the cable will become excessively heated and deteriorate the insulation, possibly burning it out. Table 7-2 shows cables and their allowable currents for your reference.

2. Cable length
   If a long cable is used, a voltage drop occurs due to the increased resistance in the conductors decreasing the input voltage to the load (electrical product). As a result, the load can be damaged. Table 7-2 shows voltage drops per 100 meters of cable.

8-1-1 “Dr. ROBIN” GENERATOR TESTER

The “Dr. Robin” generator tester is exclusively designed for fast, easy diagnosis and repair of Robin generators.

The “Dr. Robin” has the following features:
1. Functions of voltmeter, frequency meter, megger tester, capacitance meter and circuit tester are combined in one unit.
2. Fast and easy readout by digital indicator.
3. Built-in automatic battery checker indicates the time to change batteries.
4. Tester and accessories are installed in a handy, sturdy case for easy carrying.

Table 8-1

The “Dr. Robin” generator tester can be ordered from Robin generator distributors by the following part number.

Dr. Robin Part Number : 388-47565-08

If you do not have a “Dr. Robin” generator tester, use the instruments described in the following section for checking generator parts.
8-1-2 INSTRUMENTS

(1) VOLTMETER
AC voltmeter is necessary. The approximate AC voltage ranges of the voltmeters to be used for various types of generators are as follows:
- 0 to 150V: Type with an output voltage of 110 or 120V
- 0 to 300V: Type with an output voltage of 220, 230 or 240V
- 0 to 150V, 0 to 330V: Dual voltage type

(2) AMMETERS
AC ammeter is necessary. An AC ammeter with a range that can be changed according to the current rating of a given generator is most desirable. (About 10A, 20A, 100A)

(3) FREQUENCY METER
Frequency range: About 45 to 65Hz
NOTE: Be careful of the frequency meter's input voltage range.
(4) **CIRCUIT TESTER**  
Used for measuring resistance, etc.

(5) **MEGGER TESTER**  
Used for measuring generator insulation resistance.  
Select one with testing voltage range of 500V.

(6) **TACHOMETER**  
Use the contactless type tachometer.
8-2 AC OUTPUT MEASURING

Use a circuit like the shown in Fig. 8-8 for measuring AC output. A hot plate or lamp with a power factor of 1.0 may be used as a load. Adjust the load and rpm and check that the voltage range is as specified in Table 8-2 at the rated amperage and rated rpm.

Table 8-2

8-3 DC OUTPUT MEASURING

Measurement of DC output is executed with the switch turned ON while the current is regulated at 8.3A by adjusting the load to the generator. If the voltage is within the range from 6V to 14V, the voltage output is normal.

Note: If a battery is connected as a load to the generator, the DC output voltage will increase by approximately 1 to 2V. Therefore, carefully observe the electrolyte level and do not overcharge the battery.
8-4 MEASURING INSULATION RESISTANCE

Use a "Dr. Robin" generator tester in megger tester mode or use a megger tester to check the insulation resistance. Connect a megger tester to one of receptacle output terminals and the ground terminal, then measure the insulation resistance. An insulation resistance of 1 megohm or more is normal. (The original insulation resistance at the time of shipment from the factory is 10 megohm or more.) If it is less than 1 megohm, disassemble the generator and measure the insulation resistance of the stator, rotor and control panel individually.

- STATOR
  (1) Measure the insulation resistance between BLUE lead and the core.
  (2) Measure the insulation resistance between WHITE lead and the core.
  (3) Measure the insulation resistance between YELLOW lead and the core.
  (4) Measure the insulation resistance between BROWN lead and the core.

- ROTOR
  Measure the insulation across one of the soldered terminals of the rotor and the core.
- CONTROL PANEL

Measure the insulation resistances between the live parts and the grounded parts.

Any part where the insulation resistance is less than 1MΩ has faulty insulation, and may cause electric leakage and electric shock.
Replace the faulty part.
9. CHECKING FUNCTIONAL MEMBERS

9-1 VOLTMETER

Check the voltmeter if it is turned on by applying specific voltage. Voltmeter cannot be checked with circuit tester because its resistance is too large.

9-2 AC RECEPTACLES

Using a “Dr. Robin” or a circuit tester, check continuity between the two terminals at the rear of the AC receptacles while the receptacle is mounted on the control panel. When continuity is found between the output terminals of the receptacle with a wire connected across these terminals, the AC receptacle is normal. When the wire is removed and no continuity is found between these terminals, the receptacles are also normal.
9-3 NO-FUSE BREAKER
Check continuity between each of two terminals at the rear of the No-Fuse breaker while it is mounted on the control panel. Normally, there is continuity between each of the two when the No-Fuse breaker is on while there is no continuity when the No-Fuse breaker is off.

9-4 STATOR
Disengage connectors on the wires from stator and check the resistance between wires with a “Dr. Robin” or a circuit tester refering to the following table.

Table 9-1
NOTE: If the circuit tester is not sufficiently accurate, it may not show the values given and may give erroneous readings.
Erroneous readings will also occur when there is a wide variation of resistance among coil windings or when measurement is performed at ambient temperatures different from 20°C(68°F).
9-5 ROTOR ASSEMBLY

(1) Using a “Dr. Robin” or a circuit tester, measure the resistance of the field coil at the terminals.

<td>1.88 Ω</td>

<td>1.62 Ω</td>
</tr>
</tbody>
</table>

Table 9-2

NOTE 1: Because a diode is soldered to the coil ends at the terminals, resistance may be measured only when tester probes touch the terminals in one combination of polarity. Therefore, if no resistance reading appears, try checking in reverse polarity.

NOTE 2: If the circuit tester is not sufficiently accurate, it may not show the values given and may give erroneous readings. Erroneous reading will also occur when there is a wide variation of resistance among coil windings or when measurement is performed at ambient temperatures different from 20°C (68°F).

9-6 CONDENSER

- Use a “Dr. Robin” in capacitance meter mode to check the capacity of condensers. (See Fig. 9-6).

NOTE: Be sure to discharge condensers by shorting condenser leads each other before checking their capacitance, or the accurate reading cannot be obtained.
If such an instrument is unavailable, the condenser can be checked by replacing with a new one. If the generator performs good with new condenser, the cause of trouble is defect in original condenser.

**9-7 DIODE RECTIFIER**

Circuit inside of the diode rectifiers is as shown in Fig. 9-9. Check continuity between each terminal by using a circuit tester as shown in Fig. 9-10. The rectifier is normal when continuity is as follows:

Table 9-4-2

NOTE 1: Because of the difference of measuring method between the analogue circuit tester and the digital circuit tester, polarity of tester needles should be reversed.

NOTE 2: "Continuity" means forward direction characteristics of the diode, and different from short circuit condition (in which a pointer of the tester goes out of its normal scale), shows resistance to some extent. When results of the checking indicates failure even in one section, replace with a new one.

NOTE 3: Simpson brand analogue testers have the characteristics as same as the digital circuit tester.

9-8 OIL SENSOR (OPTION)
1. Disconnect two (2) wires coming from the sensor at the connection.

2. Loosen the sensor to remove it from the engine.

3. Plug the opening of oil filler hole (created after sensor is removed) with suitable means such as oil gauge.

4. Connect the removed wires again with the oil sensor.

5. Start the engine with the oil sensor removed and confirm if;
   a. Engine stops after 5 seconds which is normal, or
   b. Engine does not stop after more than 10 seconds which is unusual.

NOTE: The sensor will not operate properly when wire is broken or poorly connected. Check the wires for correct connection. If it fails to stop within 5 seconds after the wirings have checked, the sensor is wrong. Replace the sensor with new one.
10. DISASSEMBLY AND ASSEMBLY

10-1 PREPARATION and PRECAUTIONS

1) Be sure to memorize the location of individual parts when disassembling the generator so that the generator can be reassembled correctly. Tag the disassembled part with the necessary information to facilitate easier and smoother reassembly.

2) For more convenience, divide the parts into several groups and store them in boxes.

3) To prevent bolts and nuts from being misplaced or installed incorrectly, place them temporarily back at their original position.

4) Handle disassembled parts with care; clean them before reassembly using a neutral cleaning fluid.

5) Use all disassembly/assembly tools properly, and use the proper tool for each specific job.

   M4 screw .............. 8 pcs. (RGX5510)
(2) Disconnect the connectors on the wires to detach the control panel and box.
(3) Remove the condensers and diode rectifier from the control box.
(4) After disconnecting individual wires, remove the control panel components.
   NOTE: DC fuse, full power switch and pilot lamp have their wires soldered. Unsolder them to remove those parts if necessary.

10-4-3 REASSEMBLY
(1) Install the receptacles, no-fuse breaker, fuse, terminals, switches, etc. on the control panel and wire them.
   NOTE: Circuit diagrams are shown in Section 12. Colored wires are used for easy identification, and are of the correct capacity and size. Use heat-resistant type wires (permissible temperature range 75°C or over) in the specified gauge shown in the circuit diagrams.
(2) Install condensers, and diode rectifier into the control box.
(3) Connect the wires of control panel components and control box.
   Fasten the earth wires to the rear of the control box using a M4 nut to the bolt which fixes the condenser bracket to the inside of the control box. (See Fig.10-30.)

11-2-3 CHECKING STATOR

Check stator referring to Step 11-1-2.

11-2-4 CHECKING ROTOR

Check rotor referring to Step 11-1-3.
11-3 AC VOLTAGE IS NORMAL AT NO-LOAD, BUT THE LOAD CANNOT BE APPLIED.

11-3-1 CHECK THE ENGINE SPEED.
If the engine speed is low, adjust it to the rated r.p.m.
* Refer to Step 11-2-1 for engine speed adjustment.

11-3-2 CHECK THE TOTAL WATTAGE OF APPLIANCES CONNECTED TO THE GENERATOR.
Refer to Section 7 “RANGE OF APPLICATIONS” for the wattage of the appliances.
If the generator is over-loaded, reduce the load to the rated output of the generator.

11-3-3 CHECK THE APPLIANCE FOR TROUBLE.
If the appliance is faulty, repair it.

11-3-4 CHECK IF THE ENGINE IS OVERHEATED.
If the cooling air inlet and/or cooling air outlet is clogged with dirt, grass, chaff or other debris, remove it.

11-3-5 CHECK THE INSULATION OF THE GENERATOR.
Stop the engine. Measure the insulation resistance between the live terminal of the receptacle and the ground terminal.
If the insulation resistance is less than 1 MΩ, disassemble the generator and check the insulation resistance of the stator, rotor and the live parts in the control box. (Refer to Section 8-3.)
Any part where the insulation resistance is less than 1 MΩ, the insulation is faulty and may cause electric leakage.
Replace the faulty part.

11-4 NO DC OUTPUT

11-4-1 CHECK THE AC OUTPUT.
Check the generator by following Step 11-1-1 through Step 11-1-3.
11-4-2 CHECK THE DC FUSE.
Check the fuse in the fuse holder.
If the fuse is blown, check for the cause of fuse blowing, and then replace with a new one.
FUSE : 10A
NOTE: If the DC output is used to charge a large capacity battery or an over-discharged battery, an excessive current may flow causing fuse blow.

11-4-3 CHECK THE WIRING.
Check all the wires to be connected correctly.

11-4-4 CHECK THE DIODE RECTIFIER.
Remove the control panel and check the diode rectifier with a circuit tester.
Refer to Section 9-7 “DIODE RECTIFIER” for the checking procedure.

11-4-5 CHECK THE DC COIL
Check the resistance between two brown leads from stator with a circuit tester.

Table 11-3

If the resistance reading is much larger or smaller than the specified value, the DC coil of the stator is faulty. Replace stator with a new one.
11-5 IDLE CONTROL (Option for 60Hz only)

11-5-1 ENGINE SPEED IS NOT INCREASED WHEN A LOAD IS APPLIED

(1) Inspect the solenoid bracket.
   Check the bend angle of solenoid bracket.
   If the bracket is distorted, correct the angle with proper tool.

(2) Check the wattage of load applied to the generator.
   If the generator is loaded over the rated wattage, the engine speed can not be increased.
   Most induction loads such as electric motor or electric tools or welding machine require three to five times large wattage of their ratings at starting.
   This starting wattage must not exceed the rated output of the generator.

(3) Check the slow set r.p.m.
   The normal idling speed by the IDLE CONTROL is as follows:
   RGX2410, 3510 ........ 3150 - 3200 r.p.m.
   RGX5510 .............. 2700 - 2800 r.p.m.
   Adjust the idling speed monitoring the voltmeter so that it indicates between 75 volt and 85 volt.
   • Turn the adjusting screw to adjust the slow speed.

(4) Check the wiring through ZCT on the IDLE CONTROL UNIT BOARD.

- Single Voltage Type
  Make sure that an output wire from main coil is passing through the ZCT on the IDLE CONTROL UNIT.

- Dual Voltage Type
  Check that two output wires (black wire and red wire) from main coils are passing through the ZCT on the IDLE CONTROL UNIT in the same direction.

(5) Checking the IDLE CONTROL UNIT
Check the resistance between six leads of IDLE CONTROL UNIT with circuit tester.

**Table 11-4**

**NOTE**: Take ±10% tolerance on above resistance value.
If the measurement differs largely from normal value, the IDLE CONTROL UNIT is defective.
Replace with a new one.
11-5-2 ENGINE SPEED IS NOT REDUCED WHEN LOAD IS OFF.

(1) Check the distortion of the SOLENOID BRACKET as shown in step 11-5-1-(1).

(2) Check the FUSE on wiring of IDLE CONTROL UNIT.
   - Remove the control panel from control box.
   - Check the FUSE in the fuse holder of IDLE CONTROL UNIT.
     If fuse is blown, replace with a new one. (FUSE : 0.3A)

(3) Check the wiring of SOLENOID.
    Check two leads from SOLENOID are securely connected.

(4) Check the wiring of IDLE CONTROL UNIT.
    Check all leads from IDLE CONTROL UNIT are securely and correctly connected.

(5) Checking the SOLENOID.
    Measure the resistance between two leads from SOLENOID.
